Turk *māh*), moon, month The relations of these forms to each other, and to the words for 'month' (see *month*), and their ult. root, are undetermined The usual explanation is that the moon is the 'measurer' (sc. of time), < √ *ma*, Skt *mā*, measure (whence ult E *metel* and *measure*). The L. name of the moon (*luna*) and the L, Gr, and Teut. names for the sun (L *sōl* = AS. *sōl*, etc, Gr *ἥλιος*, AS *sunne*, E *sun*, etc) come from other roots, meaning 'shine'] **1** A heavenly body which revolves around the earth monthly, accompanying the earth as a satellite in its annual revolution, and shining by the sun's reflected light. Next to the sun, the moon is the most conspicuous and interesting of celestial objects. The rapidity of its motion, the variety of its phases, and especially the striking phenomena of eclipses, compelled the attention of the earliest observers, and the fact that lunar observations can be made available to determine the longitude has given the theory of the moon's motion the first rank in economic importance, while the mathematical problems involved have proved most interesting and fertile from the scientific point of view Of all the heavenly bodies (meteors excepted) the moon is nearest to us Its mean distance is a little more than sixty times the radius of the earth, or 238,800 miles. The dimensions of the moon as compared with those of the earth are far greater than those of any other satellite in proportion to its primary Its diameter is 2,162 miles (about 0.273 of the earth's equatorial diameter), and its volume, or bulk, is 0 0204, or about one forty ninth of that of the earth Its mean density, however (about 3 4 times that of water), is only about three fifths of that of the earth, and its mass about one eightieth The inclination of its orbit to the ecliptic is 5° 8′ 40″. It completes its revolution around the earth in an average period of 27d 7h 43m 11 5s, which constitutes the *sidereal* month, the ordinary, or *synodical*, month, from new moon to new moon again, is a little more than two days longer—29d 12h 44m 2 7s (See *month*) The moon's orbital motion is subject to considerable inequalities, due to the disturbing action of the sun, and the investigation of these inequalities makes up the major part of the "lunar theory." The moon revolves on its axis once in a sidereal month, thus always presenting nearly the same face to the earth—a circumstance which has led to the fallacy of a denial of its rotation (See *rotation*) Its disk appears to the naked eye diversified by dark and bright patches, giving rise to the "man in the moon" of popular fancy (see under *man*), but on examination with a powerful telescope these are lost sight of, and replaced by a crowd of interesting objects such as mountains and valleys, craters and clefts, on a scale unknown upon the earth the surface structure seems to be mainly volcanic, resembling very closely in certain respects, and differing most markedly in others from, that which is characteristic of volcanic regions on the earth's surface The moon has no clouds, shows no indications of an atmosphere or of the presence of water, and is believed to have a temperature which at its maximum does not rise above the melting point of ice. See *libration*.

over by a president and two counselors whose authority extends over the entire church, and it includes the twelve apostles, the seventies, the patriarch, the high priests, and the elders The twelve apostles constitute a traveling high council, which ordains other officers and is intrusted with general ecclesiastical authority, the seventies are the missionaries and the propagandists of the body, the patriarch pronounces the blessing of the church, the high priests officiate in the offices of the church in the absence of any higher authorities, and the elders conduct meetings and superintend the priests The Aaronic priesthood includes the bishops, the priests, the teachers, and the deacons, the two last named are the subordinate orders in the church. The duties of the bishops are largely secular The entire territory governed by the church is divided and subdivided into districts, for the more efficient collection of tithes and the administration of the government The Mormons accept the Bible, the Book of Mormon, and the Book of Doctrine and Covenants as authoritative, and regard the head of their church as invested with divine authority, receiving his revelations as the word of the Lord They maintain the doctrines of repentance and faith, a literal resurrection of the dead, the second coming of Christ and his reign upon earth (having the seat of his power in their territory), baptism by immersion, baptism for the dead, and polygamy as a sacred duty for all those who are capable of entering into such marriage The Mormons settled first at Kirtland, Ohio, then in Missouri, and after their expulsion from these places in Nauvoo, Illinois, in 1847–8 they removed to Utah, and have since spread into Idaho, Arizona, Wyoming, etc They have frequently defied the United States government There is also a comparatively small branch of the Mormon Church, entitled "The Reorganized Church of Jesus Christ of Latter-day Saints," which is opposed to polygamy and is ecclesiastically independent of the original organization Also *Mormonist*, *Mormonite*. —**Book of Mormon**, one of the authoritative writings of the Mormon Church According to the Mormons, it is the record of certain ancient peoples in America, abridged by the prophet Mormon, written on golden plates, and discovered by Joseph Smith at Cumorah (western New York), and translated by him By anti Mormons it is generally regarded as taken from a romance written about 1811 by Solomon Spaulding, whose manuscript was used by Smith and Rigdon.

morter, MHG *mortære*, *morter*, *mortel*, G *mortel*, < L *mortarium*, mortar, a mixture of lime and sand, so called from the vessel in which it was made, a mortar see *mortar*[1]] A material used (in building) for binding together stones or bricks so that the mass may form one compact whole The use of mortar dates back to the earliest recorded history, but various materials were employed for that purpose "Bitumen" (asphaltum and maltha), or bituminous mixtures, are known to have been used in Babylon and Nineveh Plaster (calcined sulphate of lime) was the cement employed on the Great Pyramid, and apparently by the Egyptians generally, but not to the entire exclusion of what is now ordinarily called *mortar* The substances mentioned are frequently designated as *mortar* in non-technical works What is now generally understood by the term among builders and architects is a mixture of lime with water and sand, in various proportions, according to the "fatness" of the lime and the desire to economize the more costly material This kind of mortar was well known to both Greeks and Romans. Mortar made of ordinary lime "sets" (hardens) in the air (not under water) and slowly, since the absorption of carbonic acid and the consequent conversion of the hydrate of lime into the carbonate is by no means a rapid process The hardening of the mortar depends in large part on the crystallization of the carbonate of lime around the grains of sand, by which these are made to cohere firmly hence, a clean sand of which the grains are angular is of importance in forming a durable mortar The kind of mortar which sets under water is sometimes called *hydraulic mortar*, but is more generally known as *hydraulic cement*, or simply *cement* See *cement* and *cement stone*

See *line*² —**Local motion** See *local* —**Lost motion**, in *mech* , any difference of motion between the driving parts of a motor and the driven machine, or between the parts of a machine that communicate motion from one to another It results from faulty construction of the parts, or from looseness of the boxes of axles or shafting or of a belt, which is thus permitted to slip —**Natural motion**, an involuntary movement of the body, as the beating of the heart —**Overhead motion**, a mechanism, consisting of countershafts and speed pulley arrangements of gears or any other contrivances, for increasing speed or force, interposed between some prime mover or main line of power-transmission and a machine with which it communicates It is so called because, for convenience in transmission, or that it may not occupy working space it is placed over the machine affected by it Also called *overhead work* —**Paracentric motion**, motion to or from an attracting center —**Parallel motion** (*a*) See *parallel* (*b*) In *music* See def 14 (*b*) —**Passive motion**. See under *active motion* —**Perpetual motion**. (*a*) A machine which should do work without exhausting any power of doing work - that is, its work must not be accompanied by any displacement (such as the fall of a weight, or the uncoiling of a spring) or transformation (such as the combustion of fuel) which could not be undone by a replacement or counter transformation without the expenditure of as much work as the machine has done Such a machine is impossible, and contrary to all experience, for power of doing work is never increased nor diminished Nevertheless, very many pretended perpetual motions have been put forth by deluded or knavish inventors Most of them are of two classes —1st, those which depend upon gravity or magnetism, and, 2d, those which depend upon centrifugal force or other pressure mistaken for moving power (*b*) The mode of motion of such a machine (*c*) By a popular abuse of the term a movement or machine which could go on indefinitely by its own self generated power Thus, if a man should pretend to have a wheel which turned upon its bearings without resistance, so that it would go on moving indefinitely, or to have a fluid which, though viscous, was fluidless, so that its motion, though continually decreasing, never came to rest, neither claim would be a claim to a perpetual motion, nor (however unfounded) would it violate any fundamental principle of mechanics On the other hand, a machine (such as has actually been proposed) which would not go on moving of itself forever, but would require a little external force to overcome friction, but which with that little force should be capable of doing an indefinite amount of work, would, properly speaking, be a perpetual motion —**Positive motion**, in *mech* , an arrangement of apparatus connecting related parts of a machine in such manner that, as one moves, the other must move in accordance with the law of the relation For example, the system of gearing which takes motion from the lathe-spindle, and imparts motion to the lead screw of a lathe, is a positive motion On the other hand, any mechanism which moves a part of a machine in a manner that permits the possibility of some subsequent motion, or variation of the motion, of the part, through the action of any force not directly transmitted by such mechanism, is not positive Examples of motions not positive are -the mechanism actuating a tilt hammer, which falls by its gravity , a spring which by its elasticity reverses, and pulleys driven by belts in which the motion may be varied through slip **Positive-motion loom** See *loom*¹ —**Primary motion**, the diurnal motion of a fixed star —**Proper motion**, in *astron* , that apparent motion or angular velocity of a fixed star which is due to a real movement of the star itself relatively to the other stars.—**Quantity of motion**, momentum, the sum of the velocities of all the particles each multiplied by the mass —**Rectilinear, parabolic**, or **circular motion**, motion in a rectilinear, parabolic, or circular path —**Relative motion**, change of relative place **Retrograde motion**, in *astron* , decrease in the longitude of a star —**Rotatal motion** See *vortex motion* —**Secondary motion**, the proper motion of a fixed star —**Simple harmonic motion**, a motion like a uniform motion round the circumference of a circle which is looked at edgewise "when a point Q moves uniformly in a circle, the perpendicular QP drawn from its position at any instant to a fixed diameter AA′ of the circle intersects the diameter at a point P, whose position changes by a *simple harmonic motion*" *Thomson and Tait* —**Slide-valve motion**, in a steam engine, broadly, the valve-gear any one of a great variety of devices for imparting to a slide valve its proper motion for induction, cut off, exhaust, and compression or cushioning Strictly at the end of the gear, and especially, the motion of a slide-valve produced by the valve-gear The link motion is one of the most important of valve gears In the majority of slide valve motions the primary movement is derived from an eccentric keyed to the crank shaft. In other cases motion is taken from the cross-head In the Joy valve gear the primary movement is obtained from the connecting-rod See *induction, cut off, exhaust, eccentric*, and *valve-gear* - **Take-up motion**, in a loom the mechanism which takes up and winds the woven cloth on the cloth beam as fast as the warp is unwound from the warp-beam The name is also given to analogous mechanism in many other kinds of machines —**Violent motion**†, in older writers, a motion impressed upon a body by an external force.—**Voluntary motion**, motion ensuing on an act of will, in contrast with reflex action or motion = **Syn.** *Motion Movement, Move.* *Motion* may be considered separate from that which moves, *movement* is always connected with the person or thing moving hence we speak of the laws of *motion*, of heat as a mode of *motion*, and of perpetual *motion* — not of *movement* in any of these cases, hence, also, *motion* is the more scientific and technical term *Motion* is more general and more voluntary, *movement*, more particular and occasional hence we speak of a *motion* with the hand, a *movement* of troops, involuntary *movements*, the *movements* of the heavenly bodies, the rate of *motion* or of *movement*. The figurative uses of the two correspond to the literal. The chief uses of *move* are founded upon the idea of moving a piece, in chess or a similar game, for winning the game

II. *n.* **1** A mental state or force which induces an act of volition, a determining impulse, specifically a desire for something, a gratification contemplated as the final cause of a certain action of the one desiring it The term *motive* is also loosely applied to the object desired The noun *motive*, in this sense was brought into general use by writers influenced by Hobbes (though he uses the adjective only), who held that men's actions are always governed by the strongest motive, and denied the freedom of the will It is now, however, in common literary and conversational use, apart from any theory

What moves the mind, in every particular instance, to determine its general power of directing to this or that particular motion or rest? And to this I answer: the *motive*, for continuing in the same state or action is only the present satisfaction in it, the *motive* to change is always some uneasiness
Locke, Human Understanding, II xxi § 29

Without another life, all other *motives* to perfection will be insufficient *Bp. Atterbury*, Sermons, I. xi., Pref

By *motive*, I mean the whole of that which moves, excites, or invites the mind to volition, whether that be one thing singly, or many things conjunctly
Edwards, On the Freedom of the Will, I 2.

When the effect or tendency of a *motive* is to determine a man to forbear to act it may seem improper to make use of the term *motive*, since *motive*, properly speaking, means that which disposes an object to move We must however, use that improper term, or a term which, though proper enough, is scarce in use, the word determinative
Bentham Introd to Morals and Legislation, x 3, note

6. In *civil engin.*, in excavations, a piece of the original ground left at intervals to show the depth.—**Indian mounds**, earthworks erected by the aborigines of North America, the so-called mound builders. They are especially numerous in that part of the United States which lies between the Great Lakes on the north and the Gulf of Mexico on the south and is bounded on the west by the States lining the western bank of the Mississippi river, and on the east by a line drawn through the middle of the States of New York and Pennsylvania and extending southward so as to include the greater part of the two Carolinas and the whole of Georgia and Florida. Some of these works are very extensive and of varied character, consisting of mounds or tumuli, either conical or truncated, together with embankments or walls of earth or stone, which inclose areas of great size, and not infrequently are accompanied by wide and deep ditches. Thus the work at Newark, Ohio, covers an area of two square miles and consists of a network of hillocks and lines of circumvallation. So far as is known, some of these works were used as burial places and as the sites of rude dwellings and cabins, others were intended, no doubt, for purposes of defense, and others, again, may have been connected in some way with religious rites and ceremonies. Many of them were situated in the river-valleys, and not a few of the most prosperous cities in the Mississippi valley occupy sites once taken up by them.

I venture the assertion that not only has there not, as yet, been anything taken from the *mounds* indicating a higher stage of development than the red Indian is known to have reached, but that even the *mounds* themselves,

and under this head are included all the earthworks of the Mississippi Valley, were quite within the limits of his of forts *L Carr*, Mounds of the Mississippi Valley, p. 3.

See cut under *Megapodius*.

mound-builder (mound'bil'dėr), *n.* 1. One of a race of people by whom the various earthworks called *Indian mounds* (see *mound*[1]) were constructed. That these works are not necessarily of great antiquity, and that they were built by a race in no essential respect different from that found inhabiting the region where they occur when this was first settled by the whites, is the present opinion of nearly all the best-informed investigators of American archæology. See quotation under *Indian mounds*, above.

In districts where the native tribes known in modern times do not rank high even as savages, there formerly dwelt a race whom ethnologists call the *Mound Builders*, from the amazing extent of their mounds and enclosures, of which there is a single group occupying an area of four square miles. *E B Tylor*, Prim Culture, I. 50

An elevation of land of considerable dimensions rising more or less abruptly above the surrounding or adjacent region. Ordinarily no elevation is called a mountain which does not form a conspicuous figure in the landscape, hence, what is a mountain in one region might be regarded as simply a hill in another. A region may have great elevation above the sea level, but not be recognized as a mountain. Thus, the Plains, or the region between the Missouri and the Rocky Mountains, have an elevation on their western edge as great as that of the highest points of the Appalachian range. Elevated regions not mountains are often called *plateaus*. Elevations, although of considerable height, if quite isolated or precipitous, are often called *rocks*: as, the *Rock* of Gibraltar. *Peak* is occasionally used in the same way as Pike's *Peak*, the *Peak* of Teneriffe, and in the United States, in regions formerly occupied or explored by the French, the word *butte* is employed with a somewhat similar meaning, while *mound* is used over a considerable extent of country, especially in Wisconsin, as nearly the equivalent of *butte* or *mount*. For ranges or connected series of mountains, see *mountain-chain*.

mountain-chain (moun'tăn-chān), *n* A connected series of mountains or conspicuous elevations. In the formation of mountains other than volcanic the process has usually been of such a character that a long strip of country has been raised in a sort of crest or wall, indeed, regions thousands of miles in length have occasionally been thus affected This elevated ridge or wall has either in the original process of mountain building been raised into masses or subdivisions of varying height and more or less isolated from each other, or else long continued erosion and exposure to atmospheric agencies have brought about the same result The more or less-separated and distinct peaks, summits, or crests together make up the range It is impossible to establish any criterion by which one mountain range can be separated from another adjacent one In most cases, however, there is more or less similarity, if not absolute identity, between the different parts of a range, from both a geological and a topographical point of view, but there are ranges which are made up of parts differing from each other greatly in lithological character and in the epoch of their formation, and which, nevertheless, are always popularly considered as forming one system, and are so designated this is the case with most of the greater mountain-chains, as the Himalayas, the Andes, and the Cordilleras

The Roman liturgy was made compulsory in Spain, with the exception of a few churches, about A D 1100, and in the thirteenth and succeeding centuries the national liturgy had fallen into almost entire disuse The inappropriate epithet *Mozarabic* — that is, 'Arabizing' — may have been given to this liturgy from its longer retention in that part of Spain which was held by the Moors, or may have been meant as an unfavorable reflection upon it by the friends of the Roman rite Apart from obvious Roman insertions, this liturgy is found to agree with canons of early Spanish councils, especially that of Toledo in A D 633, and with an account of the Spanish liturgy given by St. Isidore of Seville at about the same date The Mozarabic liturgy closely resembles the Gallican liturgies, belongs with them to the Ephesine, Gallican, or Hispano Gallican group of liturgies, and, as the only full and complete extant member of that group, serves as its type and representative Among the marked peculiarities of this liturgy are —(1) the nature, arrangement, and unequaled variability of its parts, (2) its Oriental affinities, such as remains of the epiclesis, proclamations by the deacon, the position of the pax, the presence of the Sancta Sanctis, etc, (3) the elaborate ritual of the fraction, and (4) the use of a peculiar nomenclature for the parts, considerably different even from that of the Gallican uses, as, for instance, *officium* for *introit sacrificium* for *offertory anthem*, *ilation* for *preface*, etc See *Ephesian*, *Gallican*, *liturgy* — **Mozarabic office**, the office for the canonical hours according to the ancient Spanish rite, as given in the breviary published by Ximenes in A D 1502. — **Mozarabic rite**, the Mozarabic office and liturgy

It yields a pleasant dark colored fruit, and its leaves were formerly in extensive use for feeding silkworms. The white mulberry, *M alba*, introduced from China much later, has almost superseded the black in silkworm culture. It has been to some extent introduced into the United States. The red mulberry, *M rubra*, a native of the United States, is the largest species of the genus. Its wood, which is very durable in contact with the soil, is used for posts, and for cooperage, ship and boat building, etc. Its leaves are less valued for silk production than those of the other species, but its fruit is excellent. The Mexican mulberry, extending into Texas, etc., is *M microphylla*.

The L. *mule* does not come from the AS. *mūl*, which would give a mod. form **moul* (cf. *owl*, < AS. *ūle*), it depends on the OF. or the orig. L.] 1. A hybrid animal generated between the ass and the horse. The cross is usually between a jackass and a mare, that between a stallion and a she-ass being called a *hinny*. The mule is a valuable product of artificial selection, in some respects superior to either parent, and is extensively bred in America (Kentucky, Missouri, Mexico, etc.), in Spain, in Poitou (France), etc. It retains to some extent the specific characters of the ass, in the comparatively large head, long ears, toothed mane, slim tail, and narrow, pointed hoofs; but acquires much of the size, strength, and symmetry of the mare. The animal matures slowly, is very long lived, little liable to disease, and able to do more work than a horse under hard treatment and poor fare. Being also very agile and sure-footed, it is serviceable as a pack animal in countries where a horse could scarcely be used. The mule is not less docile and intelligent than the horse, and its strength is, in proportion to its size, probably greater. Mules are ordinarily incapable of procreation, and such seems to be always the case with the jack; but instances of impregnation of the hinny by the male ass or by a stallion are not rare.

In *numis*., a coin, token, or medal which, owing to mistake or caprice, consists of two obverse or two reverse types, or of which the obverse and reverse types are accidentally associated. Thus, a denarius having a head of Tiberius on each side, or a denarius having the head of Tiberius on the obverse and a reverse type struck from one of the coin dies of Augustus, would be a *mule*.

> The encouragement given to the creation of new varieties [of English tradesmen's tokens in the eighteenth century] by combining obverse and reverse dies that had no real connection was satirized by a token bearing the reverse type of an ass [that is, a token collector] and mule saluting each other, [and] having for the legend "Be assured, friend mule you shall never want my protection." The very appropriate term *mule* was ever after applied to these illegitimate varieties.

2. An arithmetical process in which one number, the *multiplier*, is considered as an operator upon another, the *multiplicand*, the result, called the *product*, being the total number of units in as many groups as there are units in the multiplier, each group being equal in number to the multiplicand; more generally, the operation of finding the quantity which results from substituting the multiplicand in place of unity in the multiplier Thus, the multiplication of 4 by 5 gives 5 times 4, or the number of units in five groups of four units each, so the multiplication of $\frac{2}{3}$ by $\frac{2}{3}$ consists in finding $\frac{2}{3}$ not of unity but of $\frac{2}{3}$ of unity By a further generalization, multiplication in the higher mathematics is regarded as the process of bringing an operand under an operator Thus, in quaternions, if u be the operation of turning a line in a given direction through a given angle, and if v be another similar versor, then uv, or the result of the multiplication of v by u, is the rotation which would result from turning a line first through v and then through u In like manner, in the theory of differential equations, if D_x denote the operation of differentiation relatively to the variable x, and D_y denote the same operation relatively to the variable y, then the operation of differentiating first relatively to y and then relatively to x is regarded as the product of D_y by D_x, and is written D_xD_y In the algebra of logical relations, the multiplication of one relative by another consists in putting the relates of the multiplicand disjunctively in place of the correlates of the multiplier In other cases, multiplication consists in conjoining (in some specific way) each unit of the multiplier with each unit of the multiplicand and this definition may be regarded as including every other Thus, the multiplication of 2 feet of length by 3 feet of breadth is considered as giving 6 feet of area, in each of which square feet one unit of length is conjoined with one unit of breadth. So the momentum of a body having a motion of translation is said to be the product of the mass into the velocity — that is, is the result of imparting to each particle of the mass the whole of the given velocity In the Boolian algebra, the product of two classes A and B is the whole of the class embraced by both — that is, it embraces all the individuals each of which reunites the characters of A and of B. In algebra, multiplication is denoted by writing the multiplier before the multiplicand, either directly, or with a cross (×) or a dot (·) interposed between them All multiplication follows the distributive principle, expressed by the formula

$$(a + b)(c + d) = ac + bc + ad + bd$$

Under certain restrictions, all multiplication follows the associative principle, expressed by the formula $a(bc) = (ab\,c$ According to the nature of the conjunction of units, multiplication does or does not follow the commutative principle, expressed by the formula $ab = ba$

2. A certain portion of muscle or muscular tissue, having definite position and relation with surrounding parts, and usually fixed at one or both ends. Any one of the separate masses or bundles of muscular fibers constitutes a muscle, which as a whole and in its subdivisions is enveloped in fascial connective tissue and usually attached to the part to be moved by means of a tendon or sinew Muscles are for the most part attached to bones, with the periosteum of which their tendons are directly continuous The most extensive or most fixed attachment of a muscle is usually called its *origin*, the opposite end is its *insertion* Individual muscles not only change their shape during contraction, but are of endlessly varied shapes when at rest, indicated by descriptive terms, as *conical*, *fusiform*, *penniform*, *digastric*, *deltoid*, etc, besides which each muscle has its specific name Such names are given from the attachments of the muscle, as *sternocleidomastoid*, *omohyoid*, or from function, as *flexor*, *extensor*, or from position, as *pectoral*, *gluteal*, or from shape, as *deltoid*, *trapezoid*, or from some other quality or attribute, in an arbitrary manner Circular muscles are those whose fibers return upon themselves, they constitute sphincters, as of the mouth, eyelids, and anus The swelling part of a muscle is called its *belly*, when there are two such, separated by an intervening tendon, the muscle is *double bellied* or *digastric* Muscles whose fibers are set obliquely upon an axial tendon are *penniform* or *bipenniform* Muscles whose fibers are all parallel are called *simple* or *rectilinear*, those whose fibers intersect or cross each other are called *compound* Muscles which act in opposition to one another are termed *antagonistic*, those which concur in the same action are termed

D Stewart, Philos Essays, ii 5.

Mysticism is a phase of thought, or rather perhaps of feeling, which from its very nature is hardly susceptible of exact definition It appears in connection with the endeavor of the human mind to grasp the divine essence or the ultimate reality of things, and to enjoy the blessedness of actual communication with the Highest.
Encyc. Brit., XVII 128.

=Syn. 1. *Myth, Fable, Parable* See the quotation

What is a *myth*? A *myth* is, in form, a narrative, resembling, in this respect, the *fable, parable,* and allegory But, unlike these, the idea or feeling from which the *myth* springs, and which, in a sense, it embodies, is not reflectively distinguished from the narrative, but rather is blended with it, the latter being, as it were, the native form which the idea or sentiment spontaneously assumes. Moreover, there is no consciousness, on the part of those from whom the *myth* emanates, that this product of their fancy and feeling is fictitious. The *fable* is a fictitious story, contrived to inculcate a moral So the *parable* is a similitude framed for the express purpose of representing abstract truth to the imagination Both *fable* and *parable* are the result of conscious invention In both, the symbolical character of the narrative is distinctly recognized From the *myth,* on the contrary, the element of deliberation is utterly absent. There is no questioning of its reality, no criticism or inquiry on the point, but the most simple unreflecting faith

They form slimy yellow, brown, or purple (never green) masses of motile protoplasm during the period of active growth, and are then destitute of cell-wall and nucleus. Under certain conditions they secrete a cellulose wall and pass into a resting state. This resting state is brought about either by the absence of the requisite moisture, producing larger, somewhat irregular masses, the so-called sclerotium stage, or when the plasmodium seems to have concluded its vegetative period, the protoplasm then becoming heaped into a mass which breaks up internally into a large number of rounded bodies the spores, each one of which is provided with a cell wall. Under proper conditions these spores burst their walls and become motile nucleated masses of protoplasm (swarm spores) which divide separately by simple fission. After a few days two or more of these swarm spores coalesce and form new plasmodia, which differ only in size from the original. They occur on decaying logs, tan-bark, decaying mosses, etc. See *Mycetozoa*.

Egyptian Hieroglyphic | Hieratic | Phenician | Early Greek and Latin

The value of the character has been the same through the whole history of its use It stands for the "dental" nasal the nasal sound corresponding to *d* and *t*, as does *m* to *b* and *p*, and *ng* to *g* and *k* This sound, namely, implies for its formation the same check or mute contact as *d* and *t*, with sonant vibration of the vocal cords as in *d*, and further with unclosure of the passage from the mouth into the nose, and nasal resonance there Among the nasals, it is by far the most common in English pronunciation (more than twice as common as *m*, and eight times as common as *ng*) While all the nasals are semivocalic or liquid, *n* is the only one which (like *l*, but not more than half as often) is used with vocalic value in syllable making namely, in unaccented syllables, where an accompanying vowel, formerly uttered, is now silenced examples are *token, rotten, open, lesson, reason, oven*, such form on an average about one in eight hundred of English syllables The sign *n* has no variety of sounds, but before *ch, j* in the same syllable (as in *inch, hinge*) it takes on a slightly modified – a palatalized –character, and similarly it is gutturalized, or pronounced as *ng*, before *k* and *g* (hard), as in *ink, finger*, and its digraph *ng* (see *G*) is the usual representative of the guttural or back palatal nasal, which in none of our alphabets has a letter to itself *N* is doubled under the same circumstances as other consonants, and in a few words (as *kiln, damn, hymn*) is silent In the phonetic history of our family of languages, *n* is on the whole a constant sound that is to say, there is no other sound into which it passes on a large scale, but its loss, with accompanying vowel modification, has been a frequent process

In most communities of European civilization at the present day the name a person bears is double — consisting of the family name or surname and the Christian or distinctively personal name, which latter ordinarily precedes the surname, but in some countries stands last Either of these name elements may and (the personal name especially) often does consist of two or more names as component parts. An ancient Roman of historical times had necessarily two names, one distinguishing his family or gens, the *nomen*, or *nomen gentilicium*, and the other, the *prænomen*, distinguishing the individual as, *Caius Marius* — that is, Caius of the gens of the Marii Every Roman citizen belonged also to a familia, a branch or subdivision of his gens, and hence had or might have a third name, or *cognomen*, referring to the familia. This cognomen was always borne by men of patrician estate, and in the case of men of distinction a fourth name or epithet (*cognomen secundum*, or *agnomen*) was sometimes added, in reference to some notable achievement of the individual thus, *Lucius Cornelius Scipio Asiaticus* was Lucius, of the Scipio branch of the Cornelian gens, who had won personal distinction in Asia Women as a rule bore only the feminine form of the nomen of their gens as, *Cornelia*, *Tullia*. But sometimes, especially at a comparatively late date, they received also an individual prænomen, which was the feminine form of the prænomen of

the husband, or, still later, was given to them, as in the case of boys, in infancy

Proclus (tr by Cudworth), Comm in Timæum, I

Wherefore, since neither all things are produced fortuitously, or by the unguided mechanism of matter, nor God himself may reasonably be thought to do all things immediately and miraculously, it may well be concluded that there is a plastic *nature* under him, which as an inferior and subordinate instrument doth drudgingly execute that part of his providence which consists in the regular and orderly motion of matter, yet so as that there is also besides this a higher providence to be acknowledged, which, presiding over it, doth often supply the defects of it, and sometimes overrule it, forasmuch as this plastic *nature* cannot act electively nor with discretion
Cudworth, Intellectual System, I 3

3. The metaphysical principle of life; the power of growth, that which causes organisms to develop each in its predeterminate way. Aristotle defines nature as the principle of motion in those things that move themselves, meaning by motion especially generation and corruption Inasmuch as the most striking characteristic of growth is its regularity, nature is also conceived by Aristotle as the principle of inward necessity, as opposed to constraint on the one hand and to chance or freedom on the other Hence *nature* is in literature frequently contrasted with *fate* and with *compulsion*, as well as with *fortune* and *free election*

There are in sublunary bodies both constant tendencies and variable tendencies The constant Aristotle calls *nature*, which always aspires to good, or to perpetual renovation of forms as perfect as may be, though impeded in this work by adverse influences, and therefore never producing any thing but individuals comparatively defective and sure to perish The variable he calls spontaneity and chance, forming an independent agency inseparably accompanying *nature* — always modifying, distorting, frustrating the full purposes of *nature* Moreover the different natural agencies often interfere with each other, while the irregular tendency interferes with them all So far as *nature* acts in each of her distinct agencies, the phenomena before us are regular and predictable all that is uniform, and all that, without being quite uniform, recurs usually or frequently, is her work But, besides and along with *nature*, there is the agency of chance and spontaneity, which is essentially irregular and unpredictable
Grote, Aristotle, iv

The methods of solving the first are in general, four (1) by reference to one or more known and visible landmarks, (2) by ascertaining through soundings the depth and character of the bottom, (3) by calculating the direction and distance sailed from a previously determined position (see *dead reckoning*, *log*², and *compass*) and (4) by ascertaining the latitude and longitude by observations of the heavenly bodies (See *latitude* and *longitude*.) The places of the sun, moon, planets, and fixed stars are deduced from observation and calculation and are published in nautical almanacs (see *almanac*), the use of which, together with logarithmic and other tables computed for the purpose is necessary in reducing observations taken to determine latitude, longitude, and the error of the compass 3 Ships in general, shipping [Poetical]

It is more coarsely crystalline than nephelinite, to which, however, it is closely related, and it contains more augite than that rock, nephelin (which is frequently largely replaced by hauyne) and augite constituting its essential ingredients. Nephelin basalt is much more common than nephelinite, occurring in many localities in Europe. They bear axillary and terminal panicles of many small flowers, alternate evergreen abruptly pinnate leaves of a beautiful pink when young, and roundish fruit with an areolated crust partly filled within by a sweet edible pulp inclosing the bitter shining seed. As respects the New England settlers, however visionary some of their religious tenets may have been, their political ideas savored of the reality, and it was no *Nephelococcygia* of which they drew the plan, but of a commonwealth whose foundation was to rest on solid and familiar earth

3. In *her*, same as *Triton* —**4.** The outermost known planet of the solar system, and the third in volume and mass, though quite invisible to the naked eye. It was discovered in the autumn of 1846 Uranus, the planet next to Neptune, revolving about the sun in eighty four years, was discovered in 1781, but observations of it as a fixed star were scattered through the eighteenth century In 1821 Bouvard found that the observations of Uranus could not be satisfied by any theory based on the gravitation of known bodies, and hinted at an undiscovered planet. During the following twenty years further observations satisfied astronomers that such a planet must exist To find where it could be was the problem which two mathematicians, J C. Adams in England and U J J Leverrier in France, set themselves to solve by mathematics The calculations of Leverrier assigned the boundaries of a not very large region within which the unknown planet might be In consequence of the indications of Adams, the astronomer Challis observed the planet Neptune August 4th and 12th, 1846, but, neglecting to work up his observations, failed to recognize it as a planet, while, in consequence of the indications of Leverrier, Galle of Berlin discovered Neptune September 23d, 1846. The orbit of the new planet, having been determined from direct observations, was found to differ excessively from the predictions in all its elements, so much so that Leverrier declared these elements "incompatible with the nature of the irregular perturbations of Uranus" The distance from the sun was 30 times instead of 36 times that of the earth, as predicted, and the orbit, instead of being more elliptical than that of any planet except Mercury, was in fact the most circular of all When Neptune was discovered by Dr Galle it was only 1° from the predicted place, but this would not have been so at the epoch to which the calculations referred, and there was nothing in their nature to render them particularly accurate for 1846, so that this coincidence must be regarded as in great measure a happy accident, such as would occur by mere chance once in 180 times A satellite to Neptune was detected in October, 1846, by Lassell Its period of revolution is 5 days, 21 hours, and 8 minutes, and its maximum elongation 18″ The mass of Neptune, having been calculated from these data, was found to be $\frac{1}{19800}$ that of the sun, against predicted values nearly twice as great. With the mass so ascertained, the perturbing action upon Uranus was calculated, and found to satisfy the observations of that planet much better than either Leverrier's or Adams's hypothesis had done This was because the real action of Neptune upon the orbit of Uranus was of a different kind from what it had been assumed to be, those terms of the mathematical expressions which had been assumed to be the principal ones being really insignificant, and those which had been neglected as insignificant being really the controlling ones The name *Neptune* was conferred by Encke, Leverrier having signified that he wished it called by his own name The diameter of Neptune is 37,000 miles Its distance from the sun is about 2,800,000,000 miles, and its period of revolution about 164 years.—**Neptune's horse,** a fish of the family *Hippocampidæ*, a sea-horse —**Neptune's ruffles,** a tectipore **Neptune's spoonworm,** a gephyrean, *Thalassema neptuni*

nerval (ner′val), *a*. [= F. Pg. *nerval* = It *nervale*, ⟨ LL. *nervalis*, ⟨ L *nervus*, sinew, nerve: see *nerve*] Of or pertaining to a nerve or nerves, neural

nervation (nėr-vā′shon), *n* [= F. *nervation*, as *nerve* + *-ation*] The arrangement or distribution of nerves Specifically—(*a*) In *bot*, the disposition of the fibrovascular bundles in the blades of leaves, the sepals or petals of flowers the wing-like expansions of samaroid fruits, etc a character which has assumed special importance in the study of fossil plants, since it has been proved to have generic rank, while the form and outline of leaves have only specific rank The nervation of leaves as studied and classified by A P de Candolle (1827), Giuseppe Bianconi (1838), Baron von Ettingshausen (1854–61), Oswald Heer (1856), and later authors, is based primarily on the relative rank of the nerves and secondarily on their course through the leaf As regards the rank of the nerves, the leaves of dicotyledonous plants are usually either pinnately or palmately nerved. This refers to the primary nerves In pinnately nerved leaves there is only one primary nerve, the midrib, which may be regarded as a continuation of the petiole, and from which there are given off secondary nerves which proceed at various angles through the blade toward or to its margin These secondaries may or may not give off other nerves called tertiaries, and even these may produce quaternary nerves. In palmately nerved leaves there arise, usually from the summit of the petiole, two or more (sometimes numerous) more or less divergent primary nerves, which may have nearly equal strength, but more commonly the central one is thickest and may still be denominated the *midrib* In the latter case the others are called *lateral primaries* Any or all of the primaries of a palmately nerved leaf may give off secondaries as in pinnately nerved leaves, but these more commonly proceed from the outer pair Leaves of only three primaries are sometimes called *triplinerved*, those of five, *quintuplinerved* Peltate leaves usually have a peltate nervation, which may be regarded as a modification of the palmate nervation The pedate nervation is simply a case of palmate nervation in which there are several nearly equal primaries. The terms *penninerved*, *palminerved*, *peltinerved*, and *pedalinerved* were suggested by De Candolle for these several kinds of leaves As regards the course of the nerves through the blade and their ultimate disposition, the following classes are distinguished (1) *craspedodrome* [⟨ Gr *κραspεδοι*, edge, margin, + *-δρομος*, ⟨ *δραμειν*, run], the nerves passing directly to the margin of the blade, (2) *camptodrome* [⟨ Gr *καμπτος* verbal adj of *καμπτειν*, bend, curve], the nerves curving (usually forward) near the margin, and either losing themselves in the parenchyma or joining, arching, or otherwise anastomosing within the margin, (3) *brochidodrome* [⟨ Gr *βροχος* (*βροχός*), dim *βροχος*, a noose, loop], the nerves forming loops within the blade of the leaf, (4) *acrodrome* [⟨ Gr *ἄκρος*, at the point], the nerves passing upward and forward and terminating in the apex or point of the leaf, (5) *dictyodrome* [⟨ Gr *δικτυον*, a net], the nerves soon dividing up and losing themselves in the general network of the leaf (see explanation of *nervilles*, below), (6) *hyphodrome* [⟨ Gr *ὑφη*, a web], the nerves, of lower rank than primaries, so lost in the thick, coriaceous tissues of the leaf as to be nearly or quite invisible at the surface, (7) *paruphodrome* [⟨ Gr *παρυφη*, a border woven along a robe], a strong nerve passing round the entire margin of the leaf, forming a sort of hem or border (8) *marginal*, a distinct nerve passing along the margin of the leaf, parallel to it, but separated from it by a narrow interval, (9) *parallelodrome* [⟨ Gr *παραλληλος*, parallel] the nerves running parallel to one another, either longitudinally as in grasses, or horizontally from the midrib to the margin, as in the banana tree, (10) *campylodrome* [⟨ Gr *καμπυλος*, curved], the nerves passing in a gentle curve from base to apex of the leaf, the interval between them increasing gradually in width from either end to the middle The last two classes are almost wholly restricted to monocotyledonous plants. Besides the above, there is the *dichotomous* or *forking* nervation of most ferns and some other plants From the various nerves as thus described there usually proceed many much finer ones which join and anastomose in various ways, forming a network of meshes of different shapes, usually angular, and either rectangular, trapezoidal, or nearly square, the spaces inclosed by which are known as *areolæ* To such nerves the term *nervilles* has been applied Physiologically considered, all nerves consist of vascular bundles which pass from the branch through the petiole, if there is one, into the base of the leaf, the primary fascicle of which is subsequently divided up to furnish the various nerves of the leaf, the primary nerves further dividing to supply the secondaries, these to supply the tertiaries *etc*, and no nerves or fibers originate within the leaf (*b*) In *zoöl*, the arrangement or disposition of the nervures, nerves, or veins of an insect's wing, the set or system of nerves as thus arranged, neuration, venation (*c*) In *anat*, the way or mode in which the nerves are disposed as, the *nervation* of a vertebrate consists of a cerebrospinal and a sympathetic system

Icel. *nōt*, a large net. Root unknown.] **I.** *n.* **1.** An open textile fabric, of cotton, linen, hemp, silk, or other material, tied or woven with a mesh of any size, designed or used for catching animals alive, either by inclosing or by entangling them; a netting or network used as a snare or trap. Nets are of high antiquity, and there are almost as many kinds of them as there are ways in which a piece of netting or a network can be adapted to the capture of animals It is character istic of nets to take the game alive, either by surrounding or inclosing it as in a bag or by entangling it in meshes Many kinds of net are described and named — from the nature of the game, as, *bird nets*, *butterfly-nets*, *fish nets*; from the way in which the game is taken, as, *gill net*, *gill trap net*; from the way in which the net is handled or worked, as, *beating net*, *dip net*, *draw net*, *drag net*, *drift net*, *drop-net*, *hand net*, *landing net*, *set net*, *stake net*, *scoop net*, from the shape of the netting, as, *bag net*, *purse net*, etc In the fisheries in which nets are most used, many of them take other names, as *fyke*, *pound*, *seine*, *weir*, *trap* (See these words and the above compounds.) Nets range in size from a few inches to a mile or more thus, seines have been made reaching (with the ropes which haul them) 5 miles, and sweeping more than 1,000 acres of water-bottom The material ranges from the finest silk, muslin, etc, to stout cordage, gut or sinew is sometimes used The mesh is always made with a fixed, not running, knot The appliances of nets are numerous as, buoys or buoy lines to float one border of the net or indicate the whereabouts of a net under water, sinkers, leads, or lead-lines to sink one border of the net to the bottom of the water, cords or ropes for setting, stretching, hauling, pursing, etc, often worked by mechanical contrivances, as a windlass operated by horse or steam power, poles or stakes for setting, etc In some kinds of set-nets or weirs the staking or paling is so extensive in comparison with the netting that the contrivance is converted into a wooden trap, and is, in fact, called a *trap* See *net*[1], *v t*, 2

One end of a long rope passes through this ferrule, and to it are attached numerous cords extending to the lead rope The net is used by gathering up the casting rope in a coil on one arm, and taking the net itself on the other By a dexterous fling of the arm holding the net, this is thrown in such a way as to spread out completely, and it is some times hurled to a distance of many feet, so as to fall flat on the surface of the water The leads sink immediately, forming a circular inclosure, and imprisoning any fish that happen to be under it at the time The rope is then hauled in from the other end, causing the whole circumference to pucker inwardly, the leads and pucker coming together in a compact mass These nets are extensively used in the West Indies and the southern United States. —**Cast-net**, a fishing net that is cast, a casting net —**Cherry-net**, a net spread over a cherry tree to keep off birds.

Neuroptera (nū-rop'te-rä), *n. pl.* [NL., neut. pl. of *neuropterus*, ⟨ Gr. *νεῦρον*, nerve, + *πτερόν*, a wing] An order of the class *Insecta*, founded by Linnæus in 1748. It was originally composed of the genera *Libellula*, *Ephemera*, *Phryganea*, *Hemerobius* *Myrmeleon*, *Panorpa*, and *Raphidia* (*Rhaphidia*), the winged termites being included in *Hemerobius.* The group thus constituted has suffered many changes, and entomologists are still far from agreed upon its proper definition. Fabricius founded a distinct order *Odonata* for the Linnean *Libellulæ* or dragon-flies Kirby separated the Linnean *Phryganeæ* or caddis-flies under the ordinal name *Trichoptera* Erichson founded the order *Pseudoneuroptera* for those Linnean neuropters whose metamorphosis is incomplete and whose pupæ are active. These eliminations left the *Neuroptera* to consist of the families *Sialidæ*, *Hemerobiidæ*, *Mantispidæ*, *Myrmeleonidæ*, and *Panorpidæ.* By some authors the *Phryganeidæ* (the *Trichoptera* of Kirby) are still assigned to *Neuroptera*, though M'Lachlan, Brauer, and others exclude them The last-named authority has the largest following in restricting the order *Neuroptera* to the four families *Sialidæ*, *Hemerobiidæ*, *Mantispidæ*, and *Myrmeleonidæ*, forming a separate order *Panorpatæ* for the family *Panorpidæ*, and leaving the *Trichoptera* out as a separate order In this restricted sense the technical characters of the *Neuroptera* are —wings four in number and reticulate; labial palpi three jointed, the joints free, mandibles free, pupæ distinctly mandibulate, and larvæ as in *Myrmeleon.* These insects are all carnivorous in the larval state, and are either aquatic or terrestrial, the aquatic forms pupating terrestrially See cuts under *Chrysopa*, *Mantis*, and *nervure*

The fronds are simple, bipinnate or tripinnate, the pinnules rounded, heart shaped, or auriculated at the base, the median nerve sometimes almost entirely wanting, and generally disappearing altogether before the point of the pinnule is reached—the nervation diverging from the base or from the middle nerve, fan like and curving backward In several species the main stem bears rounded or kidney shaped leaflets, which were formerly referred to a distinct genus (*Cyclopteris*) The fructification of *Neuropteris* has not yet been clearly made out The genera *Neuropteris*, *Lesleya*, *Dactyopteris*, and *Odontopteris* are referred by Lesquereux to the section of *Neuropterids*

neutralization (nū′tral-i-zā′shon), *n* [= F *neutralisation*, as *neutralize* + *-ation*] **1.** The act of neutralizing, specifically, in *chem*, the process by which an acid and a base are so combined that the resulting compound has neither acid nor basic properties Thus, if a solution of sodium hydrate is carefully added to sulphuric acid, the acidity of the mixture grows less and at length quite disappears, leaving the mixture with neither acid nor basic properties. This is the *neutralization point* If more sodium hydrat is added, it imparts a basic or alkaline property to the mixture Neutralization can then be brought about only by addition of an acid In these cases the acid and base are said to *neutralize* each other The name *neutralization* is also given to the decomposition of alkaline carbonates by the addition of some stronger acid in quantity just sufficient wholly to displace carbonic acid

There are some cases in which the *neutralization* is effected by the addition of a substance which, even if added in excess, produces a precipitate, and so leaves the solution neutral, so that the addition of an excess of the precipitant is without much importance
Lea, Photography, p 425

2. (*a*) An act of one or more nations imposing upon one of their number or upon another state a condition of permanent neutrality by ordaining that it shall not take part in any war into which the others may enter, in consideration for which its freedom from attack is usually guaranteed, as in the case of Switzerland in 1815, and Belgium since its separation from the Netherlands in 1830 (*b*) An act of military powers agreeing that certain persons, property, and places, such as surgeons, chaplains, and the wounded, medical supplies, hospitals, and ambulances, shall be deemed neutral in war, and not subject to capture, etc, as was agreed by the Geneva Convention, 1864 (*c*) More loosely, the act of securing by convention immunity

for certain territory or waters from being made the scene of hostilities or of exclusive national maritime jurisdiction, as for the Black Sea, 1856, and for the Congo in Central Africa, 1885. (*d*) The condition of immunity and restriction resulting from any of such acts

Also spelled *neutralise*.

=Syn. 3 *Annul*, *Nullify*, *Annihilate*, *Neutralize* These words agree in meaning the bringing of a thing to nothing, causing it to cease to be absolutely, or as to some special relation *Annul* represents an official or authoritative act as, to *annul* an edict (See *abolish*) *Nullify*, to render invalid or of no avail, is more general and less often official a law may be illegally *nullified* by inert resistance To *annihilate* is to reduce to nothing, and should be used only where absolute putting out of existence is meant, such expressions as "his army was literally *annihilated*" are manifestly improper "his army was *annihilated*" would be proper by strong hyperbole, if the army was so broken up that no parts of it were ever gathered together again To *neutralize* is to bring to nothing in respect to some special relation, or to render inoperative or inefficacious in respect to certain other agencies or forces, by a contrary or counterbalancing force as, to *neutralize* an acid, his efforts were *neutralized* by the influence of his opponent. That which is *neutralized* would naturally have force in itself, hence we should not speak of *neutralizing* a law or a command

Νίκαια (> Νικαῖος, adj.), a name of several cities (see def.), < νικαῖος, victorious, < νίκη, victory.] Of or pertaining to Nicæa or Nice, a town of Bithynia, Asia Minor —**Nicene council**, either of two general councils which met at Nicæa. The first Nicene council, which was also the first general council, met in A. D 325, condemned Arianism, and promulgated the Nicene Creed in its earlier form. The second Nicene council, accounted also the seventh general council, was held in 787, and condemned the Iconoclasts. The recognition of the first Nicene council as ecumenical has been almost universal among Christians of all confessions, it is acknowledged to the present day not only by the Roman Catholic and the Greek churches, and by many Protestant churches, but by Nestorians, Jacobites, and Copts. The Anglican Church does not accept the second Nicene council as ecumenical —**Nicene Creed** or **Symbol**, a summary of the chief tenets of the Christian faith, first set forth as of ecumenical authority by the first Nicene council (A. D. 325), but closely similar in wording to ancient creeds of Oriental churches, and especially founded upon the baptismal creed of the church of Cæsarea in Palestine. The distinctive word added at Nicæa to exclude the possibility of an Arian construction was *homoüsion* (consubstantial), which word, however, was already in well-established theological use. This creed ended with the words *and in the Holy Ghost*, and an anathema against the distinctive tenets of the Arians was subjoined to it. The second general council — that is, the first Constantinopolitan (A. D. 381) — reaffirmed this creed, and also authorized, as subsidiary to it, an explanatory version previously formulated, probably in a local synod at Antioch, and closely similar to the baptismal creed of the church of Jerusalem, differing from the Nicene form very slightly in wording, but adding a fuller statement as to the Holy Ghost, directed against the heresy of the Macedonians, and concluding as in the form still used. At the Chalcedonian (or fourth general) council (A. D. 451), the second form was authorized equally with the first as the Nicene faith, and was officially and historically known from that time forward as the *Nicene Creed*, church historians, however, sometimes speak of it as the *Niceno-Constantinopolitan Creed*. Both these forms have been reaffirmed ever since by all councils claiming to be ecumenical. The second form came into general use in the Eastern Church in the latter part of the fifth century, and has remained unaltered in that church to the present day. It remained unaltered in the West also for some centuries, but an important addition, namely, the word *filioque*, 'and (from) the Son,' after the words *who proceedeth from the Father*, in the last paragraph, was introduced in the sixth century and, though still rejected by the Roman Church in the ninth century, had by the eleventh become accepted throughout all western Europe. It is this form, with the interpolated *filioque*, which is used by the Roman Church, the Anglican Church, and all Protestant churches which accept the Nicene Creed, and it is this last form, therefore, which is generally called by that name. The Western forms begin "I believe," not "We believe," as in the Greek. The Nicene Creed in its second form is the only authoritative creed of the Eastern Church

In ancient Roman architecture niches were generally semicircular in plan, and terminated in a semi-dome at the top. They were sometimes, however, square-headed and in classical architecture sometimes also square in plan. They were ornamented with pillars, architraves, and consoles, and in other ways. In the architecture of the middle ages niches were extensively used in decoration and for the reception of statues. In the Romanesque style they were so shallow as to be little more than panels, and the figures were frequently carved on the back in high relief. In the Pointed style they became more deeply recessed, and were highly enriched with elaborate canopies, and often much accessory ornament. In plan they are most frequently a semi-octagon or a semi-hexagon, and their heads are formed of groined vaulting, with bosses and pendants according to the prevalent architecture of the time. They are often projected on corbels, and adorned with pillars, buttresses, and various mouldings. Compare cut under *gallery*
