member of the public.***

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

Regional Variations in the Growth of Population: Introduction; Analysis of the Movements of Population; Rural Depopulation, Immigration of Foreigners

Rural Settlement: Main Types of Settlement; Geographical and Historical Factors in Settlement; Historical Development

Towns and Cities: Number and Distribution of Towns; Urban Growth; Conurbations

Note on Family Allowances

Bibliographical Note

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

(in thousands)

From P. Depoid, 'Structure Professionnelle', *Revue d'Economie Politique*, LVIII, 51 (Paris, 1939).

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture doree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loire (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

Fig. 3. The distribution of population in the Paris Basin, 1931

Based on the *Atlas de France*, Plate 73 (Paris, n.d.).

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

Fig. 4. The distribution of population in northern France, 1931

Based on the *Atlas de France*, Plate 73 (Paris, n.d.).

A, Amiens; Am, Armentieres; Ab, Abbeville; Al, Alencon; An, Anzin; Ar, Arras; B, Beauvais; Be, Bethune; Bn, Boulogne; Br, Bar-le-Duc; Bs, La Basse; By, Bruay-en-Artois; C, Caen; Ca, Cambrai; Cd, Caudry; Ch, Chalons-sur-Marne; Cm, Commerc; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Calais; Ct, Le Cateau; Cv, Carvin; Cx, Croix; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; De, Denain; Di, Dieppe; Do, Douai; Dr, Dunkirk; E, Elbeuf; Ep, Epernay; Es, Etaples; Et, Etampes; Ev, Evreux; F, Fecamp; Ff, La Fere; Fo, Fourmies; H, Hazebrouck; Ha, Halluin; Hn, Hirson; Ht, Hautmont; HL, Henin Ltetard; Hv, Havre; J, Jeumont; L, Lille; La, La Madeleine; Le, Lievin; Lm, Lomme; Ln, Laon; Lo, Longuyon; Ls, Lens; Lu, Lumes; Lv, Louviers; Lw, Longwy; M, Mantes; Ma, Maubeuge; Me, Melun; Mx, Meaux; Nr, Nogent-le-Rotrou; RT, Roubaix-Tourcoing; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; StA, St Amand; StD, St Dizier; StO, St Omer; StP, St Pol; StQ, St Quentin; To, Toul; Te, Le Treport; Tr, Troyes; V, Verdun; Va, Valenciennes; Vi, Vitry-le-Francois; W, Wattrelos.

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

Fig. 5

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

J. H. GODFREY

Director of Naval Intelligence

Chapter I

GROWTH AND DISTRIBUTION OF POPULATION

Introduction: General Features; Occupation Groups

Distribution of Population: Brittany; The Paris Basin; Northern France; Eastern France; West and South-Western France; The Central Massif; The Pyrenees; The Rhone-Sadne Valley; The Jura; The Alps; The Mediterranean Coastland

Growth of Population: The Balance of Births and Deaths; Immigration; Age Groups; Death-Rates; Birth-Rate, Fertility and Reproduction Rates; Future Trends

Regional Variations in the Growth of Population: Introduction; Analysis of the Movements of Population; Rural Depopulation, Immigration of Foreigners

Rural Settlement: Main Types of Settlement; Geographical and Historical Factors in Settlement; Historical Development

Towns and Cities: Number and Distribution of Towns; Urban Growth; Conurbations

Note on Family Allowances

Bibliographical Note

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

(in thousands)

From P. Depoid, 'Structure Professionnelle', *Revue d'Economie Politique*, LVIII, 51 (Paris, 1939).

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture doree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loire (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

Fig. 3. The distribution of population in the Paris Basin, 1931

Based on the *Atlas de France*, Plate 73 (Paris, n.d.).

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

Fig. 4. The distribution of population in northern France, 1931

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

Fig. 5

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

Fig. 6. The distribution of population in south-western France, 1931

Based on the *Atlas de France*, Plate 74 (Paris, n.d.).

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so wide-spread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

Based on the *Atlas de France*, Plates 74, 75 (Paris, n.d.).

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	-35	546	176

* Including the Saar territory.

From (1) *Annuaire Statistique, 1938 (Resumi Retrospectif)*, pp. 11-13 (Paris, 1939);
(2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	+ 4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2'0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938
0-4	82	6'8	8'1	95	103
5-9	8'4	7'2	7'2	96	10'9
10-14	8'6	7'8	8'0	9'5	11'4
15-19	5'6	8'1	7'8	9'2	97
20-24	7'3	79	69	8'5	70
25-29	80	8'4	9'1	8'3	97

45-49	6'1	6'4	6'1	5'3	45
50-54	5'8	60	5'6	48	3*9
55-59	5'5	5'5	5'0	4'2	3'3
60-64	4'8	4'7	4'5	36	7'7
65 +	9'8	8'5	7'6	67	
	100'0	100'0	100'0	100'0	100'0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	252	218	23'3	286	32'6
15-49	48'9	53'4	54'0	52'1	51'5
50 +	25'9	24'7	22'7	19'3	14'9
Women: 15-49	48'2	53'3	54'0	52'3	52'6

Of the total population men represent 48'3%; neglecting the foreigners in France, however, men represent only 47'3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations, 1938-9*, p. 44 (Geneva, 1939).
For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

*Mortality by Age and Sex: Specific Rates per 10,000

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

		M.	F.

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14·6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

	1932	1933	1934	1935	1936	1937	1938

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0.880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1.0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1.0 for the greater part of this century:

Net Reproduction Rates

1908-13	0.930	1	1935	0.866
1920-23	0.977		1936	0.88
1925-27	0.929		1937	0.87
1928-33	0.905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Net Reproduction Rates

Poland:	1931-2	1.25	France:	1935	0.866
	1934	1.11		1937	0.87
Italy:	1931	1.209	Belgium:	1936	0.831
	1935-7	1.128	England and Wales:	1935	0.764

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE Neuchatel, reproduced from the French 1 : 80,000 (1901).

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141
Over 10,000 inhabitants	341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30%, Toulouse 17%, and Strasbourg 10%; Nantes (6%) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

***Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas***

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

(in thousands)

From P. Depoid, 'Structure Professionnelle', *Revue d'Economie Politique*, LVIII, 51 (Paris, 1939).

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture d'oree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

Fig. 2

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loir (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

Fig. 3. The distribution of population in the Paris Basin, 1931

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

Fig. 4. The distribution of population in northern France, 1931

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

Fig. 5

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

Based on the *Atlas de France*, Plates 74, 75 (Paris, n.d.).

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Al, Albi; Au, Auch; Ba, Bayonne; Bi, Biarritz; Bz, Beziers; Ca, Castres; C, Carcassonne; Dx, Dax; Lo, Lourdes; Mb, Montauban; Ma, Mazamet; Mo, Mont-de-Marsan; Mt, Montpellier; Nr, Narbonne; Pa, Pau; Pm, Pamiers; Pn, Perpignan; Se, Sete; StG, St Gaudens; StJ, St Jean-de-Luz; Ta, Tarbes; To, Toulouse; V, Port-Vendres.

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	- 35	546	176

* Including the Saar territory.

(2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	+ 4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2'0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938
0-4	82	6'8	8'1	95	103
5-9	8'4	7'2	7'2	96	10'9
10-14	8'6	7'8	8'0	9'5	11'4
15-19	5'6	8'1	7'8	9'2	97
20-24	7'3	79	69	8'5	70

65 +	9'8	8'5	7'6	67	
	100'0	100'0	100'0	100'0	100'0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	252	218	23'3	286	32'6
15-49	48'9	53'4	54'0	52'1	51'5
50 +	25'9	24'7	22'7	19'3	14'9
Women: 15-49	48'2	53'3	54'0	52'3	52'6

Of the total population men represent 48'3%; neglecting the foreigners in France, however, men represent only 47'3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations, 1938-9*, p. 44 (Geneva, 1939).
For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

*Mortality by Age and Sex: Specific Rates per 10,000
Inhabitants of each Age Group*

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

		M.	F.
France:	1908-13	48.49	52.41
	1920-23	52.19	56.09

	1930-32	58.74	62.88

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 52-4 (Geneva, 1939).

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14·6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

	1932	1933	1934	1935	1936	1937	1938
Sweden	14'5	13'7	13'7	13'8	14'2	14'3	149

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0.880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1.0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1.0 for the greater part of this century:

Net Reproduction Rates

1908-13	0.930	1	1935	0.866
1920-23	0.977		1936	0.88
1925-27	0.929		1937	0.87
1928-33	0.905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Net Reproduction Rates

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE Neuchatel, reproduced from the French 1 : 80,000 (1901).

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141

Over 10,000 inhabitants 341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30%, Toulouse 17%, and Strasbourg 10%; Nantes (6%) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

***Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas***

Conurbation	Population in 000's	No. of com- munes included	Principal communes
1. Paris	5,500		
2. Marseilles	990	9	Marseilles 914; Aix 43; Aubagne 14
3. Lyons	802	32	Lyons 571; Villeurbanne 81

28. Dijon and suburbs	105		Dijon 96
29. C6te d'Azur from Cannes to Antibes	102	7	Cannes 49; Antibes 25; Vallauris 10

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

of paying family allowances encouraged the extension of the system to industry, and the shortage of labour in the years 1918-30 provided further incentive to employers to pay these allowances, in order to secure greater stability of labour by the employment of the largest possible number of married men with children. Another motive for the employers was a belief that allowances helped to withdraw family men from interest in the class struggle. To employees the scheme appeared as a means of raising their standard of living. In 1932, some 245 funds covering 1,850,000 employees, and distributing annually 380 million francs, were in operation, and affiliated to a central organization. As the number of private funds grew in these years, the rate of allowances paid to state, departmental and municipal employees increased. Eventually, in 1932, legislation was effected by which all employers were ultimately to subscribe to 'equalization' funds and to grant allowances for dependent children to all French and foreign wage earners and salaried employees.

In 1933 the number of beneficiaries amounted to 5 millions. The programme was extended to more industries, and in 1936 the system was made applicable to all industries and commercial undertakings employing more than ten people, including multiple branch concerns, while in the same year the law was extended to agriculture. The wide extension of the scheme is shown by the fact that the total payments in 1937 were 1,340 million francs, compared with 872 millions in 1936, and were estimated to reach 1,500 million francs for 1938.

Considerable variations were naturally to be found between different areas, both in the rates paid and the subscriptions levied on employers, owing to local differences in wage levels, cost of living, etc. The table on p. 79 illustrates certain rates.

When the scales were revised in 1938, it was provided that the minimum rates should be fixed by the Minister for Labour on the recommendations of the Higher Family Allowances Commission. The age to which allowances were payable for children, apprenticed or pursuing a course of studies, was raised to 17, but after November 1940, no allowance was to be payable for an only child over 5 years old. The new arrangement came into force in April 1939. ,

Machinery for Payment. Funds for the payment of family allowances are obtained entirely by subscriptions from employers. The charges amount to over 2% of the total wages bill in industry. Beginning in 1918, Equalisation Funds (*Caisses de Compensation*) came to be established as a means of regularizing the financial side. Employers contribute to the appropriate funds according to the

number of people they employ, and each fund then distributes the allowances. The Act of 1932 did not create any special machinery for the administration of family allowances, and the existing funds set up by employers were left untouched. Employers not already affiliated to equalization funds were obliged to subscribe. It is important to notice that in order to prevent employers from reducing their liabilities by employing unmarried staff, subscriptions to the funds (*caisses*) are payable for all workers, whether married or single. In 1938 a national compensation fund was established to make grants to local compensation funds, on which the charges were found to be abnormally high. The national fund, which is to be managed by the *Caisse des Depots et Consignations*, is to obtain its resources from subscriptions paid by all the local compensation funds. Until 1932 the subscriptions paid by employers were all voluntary.

Rates of Family Allowances, francs per month

	One child	Two children	Three children	Four children	Each ad- ditional child
1936: normal rate	30	70	120	200	80
1936: rate for state employees	52	76	157	196	—
1937: rate in Paris	30	80	200	400	200
1938: rate in Paris	60	160	300	500	200
1938: rates in agriculture	15 to 25	30 to 85	67'5 to 200	110 to 320	27'5 to 120
<i>Rates as percentages:</i>					
1938: rate in Paris as per- centage (approx.) of mean wage of 20 skilled trades	4	10	18	30	12
1939: minimum rate at re- vised scales for the whole of France, as percentage of adult male wage earner	5	15	30	45	15

Conclusion. It is probably too early to form a judgement upon the effectiveness of family allowances in retarding the decline of the birth-rate. The widespread application of the system has been in effect for too short a time to permit of statistically sound conclusions being drawn. As to the funds which were privately operated by firms on a considerable scale soon after 1920, such as the Michelin Company's fund for its employees at Clermont-Ferrand, it is held by some authorities that the higher birth-rate occurring among the beneficiaries of the funds represents inconclusive evidence. The employees are not a typical cross-section of the adult population as

a whole, and some of the employees may have migrated to the Michelin works so as to take advantage of the allowances.

While the payments under the schemes add to the income of parents, the addition is considerably less in amount than the increase in the cost of living incurred through-children. It has been estimated that three children add to the income of a lower grade civil servant an amount equal to only half of what they add to his cost of living. Hence it is considered by some that the scale of family allowances is too small to have any real effect upon the population position. At the most they may have resulted in a slight diminution of the rate of decline in the birth-rate. Such a view is only an opinion, and so far real knowledge cannot be arrived at until statistical investigation of the family allowance system has reached a much more advanced stage.

BIBLIOGRAPHICAL NOTE

(1) *The Census*

Vauban made an estimate of the number of inhabitants of France as long ago as 1700, and other estimates were made in 1762 and 1764. The first organized census was carried out in 1800, and in the next year, 1801, began the series of censuses, at intervals of five years, which has since been continued, except for the census of 1871, which was postponed for one year, and the census of 1916, which was not held.

When the census forms have been collected, they are first utilized to determine the figures of *population legale* in each commune, i.e. the numbers of persons having their habitual residence in the commune. The forms are then tabulated by the *Statistique Generale de la France*, and the entries analysed by category. The figures of *population presente* are obtained at this stage, i.e. the population actually present in each commune on the day of the census. In 1939 the later calculations had not been completed; only the figures of *population legale* or resident population have been published. These figures have been used in the foregoing account. The completion of the census was not expected until 1940. (See also p. 375.)

The published volume is *Resultats Statistiques du Recensement general de la population en 1936* (Statistique Generale, Paris, 1938).

Summarized statements appear in *Annuaire Statistique, 1938* (Paris, 1939).

(2) *Growth of Population*

The official account of population changes is given in *Statistique du mouvement de la population*, vol. xvi, 1936, Part 1 (Statistique Generale, Paris, 1938). Part 1 deals with marriages, divorces, births and deaths.

Chapter II

PARIS

The Site: The Growth of the City: Inner Paris: Greater Paris: Bibliographical Note

THE SITE

The successive stages in the expansion of Paris from its nucleus on an island in the Seine are closely related to the physical features of its site, and are still clearly embodied in its plan. After receiving the waters of the Maine, the Seine, cutting through a line of low heights, begins the first of its loops towards the north. On the southern bank it receives a small tributary, the Bievre, which after flowing east and north is deflected eastwards again by a low spur, the Mont Ste-Genevieve (Fig. 27). In general the relief on the south bank is broken and of moderate elevation. This broken relief imposed limitations upon the city's early development to the south, but farther to the west near the Champ de Mars a portion of the flood plain allowed expansion. Off the Mont Ste-Genevieve, in the centre of the river, lay a number of small islands, now reduced to two—lie de la Cite and lie St Louis (Plate 10). These islands, and the numerous side branches which originally characterized this stretch of the river, due perhaps to the decrease in the slope of the bed, formed a complicated pattern, but it happened that a line from the southern height across the present lie de la Cite avoided most of the obstacles.

On the north bank, the relief is in contrast to that of the south. A semicircle of heights leaves the river at Charonne on the east, and runs through Menilmontant, Belleville, Montmartre, and Chaillot, returning to the river at Passy. These heights mark the northern slopes of the Quaternary course of the Seine, the loop of which was much more pronounced than that of the present river (Fig. 27). Probably owing to changes in the course of the Marne, which increased the velocity of the Seine, the latter cut off the extremity of this loop to occupy its present course. Thus the area immediately north of the Seine is a segment of a meander plain, originally sloping not to the Seine, which cut a narrow bed through it, but towards the older course. In the early history of the city this was occupied in its western portion by a stream flowing from Menilmontant, and in its eastern end by an area of marshland, Le Marais.

The north bank therefore afforded ample space for expansion, and the growth of Paris in this direction has been closely related to this abandoned river course. At one period, portions of it were incorporated as a moat forming part of the city's fortifications. At times, too, it has proved a source of anxiety to the city engineers, for the Seine in flood has occasionally attempted to reoccupy its former bed. Thus in the floods of 1910 subsoil penetration by this channel flooded large areas round the Gare St Lazare. The original relief, however, has been largely hidden by drainage, by newly-made ground, and by buildings. It is important to note also that the northern ring of heights is not continuous: Montmartre is isolated by gaps to east and west, the former being especially important as it affords an easy line of communication northwards.

The significant features of the site therefore are the approach of the southern hills to the river, the islands in the river bed reducing the difficulty of bridging, the open plain on the north bank, and the breeches in the northern heights. The three main areas—southern heights, islands, and northern plain—have persisted from early days as subdivisions with distinct characteristics associated respectively with Universite, Cite, and Ville.

THE GROWTH OF THE CITY

The Early Medieval City

Before the Roman occupation of Gaul, the Ile de la Cite was the site of a settlement, Lutetia, the centre of a Gaulish tribe, the Parisii. By this time the Seine had been bridged and the island was close to an intersection of routes, a south-to-north land route and an east-to-west river way. Roman observers remarked upon the busy boat traffic on the river. Under Roman administration the principal section of the town was laid out on the southern bank, on the slopes of the Mont Ste-Genevieve. A Roman road from Chartres ran northwards across the lie de la Cite and up through the Montmartre-Belleville gap; on the north bank it was joined by another road descending the valley westwards from Melun, and it was around this junction that commerce was increasingly to centre.

During the first centuries of the Middle Ages however progress was slow. In the disturbed times following the Roman withdrawal and the Frankish advance, when the Roman town on the south bank was destroyed, settlement was chiefly confined to the island with two bridgeheads north and south of the river. Under the Merovingians,

in the fifth and sixth centuries, order was re-established, and with the expanding influence of the Church the elements of civilized life gradually returned. During the reign of Clovis, the basilica of SS. Peter and Paul was built on the southern quarter, and other churches soon followed (St Benoit, St Severin). Settlement on the outskirts was encouraged by ecclesiastical foundations, the abbey of St Germain TAuxerrois on the north bank, and of St Germain des Pres on a former left bank island below the city limits. The surrounding forests were gradually cleared during the ninth century, and with the revival of trade the value of the position of Paris became recognized, by none more clearly than the early rulers of the House of Capet. Indeed, it was their great achievement to establish Paris as the undisputed capital of France. By their efforts the advance of the Norsemen was stayed at the city walls after a siege during which the southern quarter was again destroyed, and their royal duchy, extending north and south of the Seine and conveniently linked by Paris, was welded together to become the foundation of the kingdom of France.*

It was to the centralizing policy of the French monarchy more than to any combination of geographical factors that the city's predominance and extraordinary growth were due. As the seat of the central government, the courts of law, and the great university of the Middle Ages, Paris drew to itself, with increasing attractive power, first the professions and trades necessary to sustain their needs, and later an industrial population to meet the demand for goods as close to the market as possible. Thus the development of Paris has been from an administrative centre to a great commercial market, and finally to an industrial concentration. The development of a planned system of roads, of canals, and of railways merely tightened the hold of Paris on the country.

The effect of this Capetian centralizing policy was soon visible in the development of the city, which during the twelfth century assumed its characteristic tripartite form. The *lie de la Cite* was the centre of royal and ecclesiastical administration. In the middle of the century the building of the new cathedral of Notre Dame was begun, and the church schools formerly grouped around it moved across to the south bank where, around the theological college founded by Robert de Sorbon in 1253, the University and its quarter crystallized. Here gathered, besides masters and scholars, the attendant scribes, followed later by the printers.

On the north bank was the 'Ville,' the predominantly commercial

* For the historical background, see vol. 11, pp. 46 et seq., of this Handbook.

Plate 10. Paris: The He de la Cite

On the island is the Palais de Justice in the foreground, with Notre-Dame Cathedral and the Hotel Dieu near the other end. There is a clear contrast between the congested streets and buildings of the 'Quartier Latin' on the left bank (on right of picture), and the more elegant tree-lined avenues and open spaces of the right bank, where the Hotel de Ville is prominent.

Plate 11. Factories at Billancourt, Paris
The great Renault works extend over a large area and have even spread to the island in the Seine.

quarter; upstream from the bridges, along the creeks and quays, grew the first 'ports' of Paris. The importance of the river traffic, which carried down to the city the wines and timber of the upper Seine basin, is seen from the growing influence of the 'Corporation of water merchants', the head of which became during the thirteenth century the chief civil officer of the municipality. The principal 'port' was on the site now occupied by the Place du Chatelet, near the Hotel-de-Ville, and close to the *croisee de Paris*, the junction of the main routes. Between the water front and the roads were established large markets, an area still partly occupied by the Halles Centrales.

The City Walls

It was around this threefold area that Philip Augustus between 1180 and 1210 built the first city wall (Fig. 27). From the eastern limit of the trading quarter on the north bank it ran in a rough semicircle, the maximum distance from the river being about 800 m., to rest in the west on the recently built fortress of the Louvre. On the south bank it enclosed the Mont Ste-Genevieve, forming the limit of the city in this direction until well into the seventeenth century. The next period of growth was therefore on the north bank, at first eastwards until the marshland along the old course of the river was reached. This marsh was gradually drained and occupied by market gardens to supply the growing city, until it was built over in the eighteenth century. The second important line of fortifications, built by Charles V about 1370, began at the Bastille and incorporated the Louvre on the west. Within the old limits the population had been growing rapidly: on a basis of a census of hearths taken in 1329 it is estimated that the population was then about a quarter of a million, a remarkable figure for the period. The new walls, however, included considerable areas of open land sufficient for some time to absorb growth which at first slackened owing to disturbed political conditions, although by the seventeenth century the city was spreading rapidly beyond the walls, mainly northwards, despite successive royal edicts establishing forbidden zones. These were partly prompted by fears of inability to feed so large a concentration, hence the preservation of the gardens of Le Marais and the attention to the water supply. The city was dependent largely upon water from the Seine, pumped directly from the river at La Samaritaine and the Pont Notre Dame. In the middle of the fourteenth century the population was nearing half a million, a stage in its development which was not materially passed until the industrial era.

The next extension of boundaries had a fiscal rather than a military reason; to facilitate the collection of the *octroi* a wall, the 'Mur des Fermiers-Generaux', was built between 1784 and 1791, with a radius some 1,500 m. larger than that of the preceding wall. This carried the northern limits of the city to the line of the old river course and

Fig. 27. The site and growth of Paris

Based on G. R. Crone, 'The site and growth of Paris', *Geographical Journal*, vol. xcvi, p. 37 (London, 1941). For the work of Philip Augustus, see vol. 11, p. 49 of this Handbook.

the foot of the northern heights. It enclosed the faubourgs which had grown up along the radiating routes and much open land, especially on the south bank. Portions of the old ramparts became the line of the great or inner boulevards.

Throughout the eighteenth century the population did not rise above half a million, but with the progress of the industrial revolution the city again pressed upon its limits. By 1841 the inhabitants

numbered 935,000, and it was then decided for military reasons to fortify a much extended area. The *enceinte* was thrown along the northern heights beyond Belleville and Montmartre and southwards towards Gentilly and Issy. This brought within the limits of Paris a number of considerable towns, for Belleville had at that time a population of 57,000 people, and Montmartre 35,000. With the incorporation in 1861 of the communes thus enclosed, the population of Paris rose to 1,690,000. The wall of the Farmers-General then became the line of the outer boulevards.

Fig. 28. The built-up area in 1839

Based on *Carte des Environs de Paris*, drawn in 1839 at the Depot Generale de la Guerre, under the direction of Lieutenant-General B. Pelet.

Industrial Growth

With industrialization and improved communications, the activities of the population also began to change markedly. Formerly, the occupation of the Parisian workers, apart from the predominating official and commercial classes, had lain mainly in trades requiring traditional skill and taste rather than an abundant supply of raw material. With the building of canals and railways, supplies of materials

for heavier industries, particularly coal and iron, became available and industry was freed from its dependence upon the river front. In the twenties there was an epoch of canal building. The Canal St Denis and the Canal St Martin were followed a few years later by the Canal de l'Ourcq. With the building of the canals the prosperity of Paris became even more closely linked to waterborne traffic, which was handled at various quays and basins along the river and the canal system, while river ports have developed up and down stream from Paris to serve the industrial suburbs, e.g. at Ivry, St Ouen, St Denis, and Gennevilliers.*

Close on the canals followed the railways. On the north bank the gaps east and west of Montmartre served as convenient routes ending at the great termini of the Gares de PEst, du Nord, and St Lazare, placed near the outer boulevards. The area enclosed in 1841 made much land available for building, and around the canal basins and stations gathered warehouses and slaughterhouses, railway goods yards and repair shops, factories and gasworks, with tenements in the neighbouring quarters to house the workers. †

While Paris was thus expanding and its industries growing, wide changes were also being made to the plan of the city. These were initiated by Napoleon III, partly on aesthetic and partly on military grounds, and the work of reconstruction was entrusted to Baron Haussmann between 1854 and 1869. Narrow streets and congested areas gave place to wide boulevards and squares (Place de l'Etoile, Boulevard St Michel); parks and gardens were laid out (Bois de Boulogne); public buildings such as the Opera were erected; and the ring of outer boulevards was built on the line of the wall of the Farmers-General. This work was naturally costly, and Haussmann met with much opposition: it is to his persistence and the emperor's support that modern Paris owes its spaciousness and its vistas.

As a result of its industrial development, the population of Paris grew rapidly after 1861, increasing by 25 % in the next twenty years. From 1881 to 1901 the rate of increase declined to about 20%, and with the beginning of this century the period of rapid expansion was approaching its close. The population reached a maximum in 1921 with a figure of 2,906,000, but this represented an increase in the preceding twenty years of 7 % only. The war of 1914-18 no doubt had

* The waterways serving Paris are more fully dealt with in vol. iv, chapter vi, of this Handbook.

† The railways serving Paris are dealt with more fully in vol. iv, chapter iv, of this Handbook.

some influence on this slowing up of the city's growth, but decline had already set in before 1911. Since 1921, the population has fallen to 2,891,000 in 1931, and to 2,830,000 in 1936, a decline of roughly 2½%. To sum up: the net result of a century of growth, 1839-1939, can be seen by comparing Figs. 28 and 29.

Fig. 29. The built-up area in 1939

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 2 (Paris, 1934), and air photographs.

Water Supply

The growth of the city has been accompanied by improvements in the water supply. Until the nineteenth century, the domestic water of Paris was drawn mainly from wells or from the Seine. The latter was raised by pumps, the first of which, La Samaritaine, was set up at the Pont Neuf in the reign of Henry IV. Later in the seventeenth century other pumps were erected at Notre Dame and at Marly for the supply of Versailles. The public fountains were, however, supplied to some extent with water from other sources, e.g. the Belleville aqueduct, said to date from the fourteenth century, and the Arcueil aqueduct, restored by Marie de Medici. These supplies were

inadequate for the expanding city, and the first step taken to obtain water from a distance was the construction in 1822 of the Canal de l'Ourcq, which for some years served as an aqueduct as well as a navigable canal. About the same time, attempts were made to utilize artesian supplies at Grenelle and elsewhere, but owing to technical difficulties these wells were abandoned. It was not until the Second Empire that the problem was solved by the engineer Belgrand, who laid the foundations of the present system. The earlier superficial supplies, were now used for public and industrial purposes, while domestic water was obtained by tapping adequate and pure supplies at the sources of distant streams; this water was led through aqueducts or underground conduits to reservoirs on the suburban heights. The first to be completed, in 1865, was that from the sources of the Dhuis, a tributary of the Marne, which carries water 114 km. to a reservoir at Menilmontant. Later, water was similarly brought from the Vanne, an affluent of the Yonne, to Montsouris (173 km.), and from the Arvre, a tributary of the Eure, to St Cloud (120 km.). More recently, Supplies for the Montsouris reservoir have been obtained from the Loing and Lunain (73 km.), and the Vanne supplies have been augmented by the Voulzie aqueduct, completed in 1925.

The water from these sources amounts to about 450,000 cu.m. per day, which is still inadequate to meet the demand, especially in summer. Some 300,000 cu.m. have therefore to be pumped from the Seine and Marne, filtered and sterilized at Saint-Maur and Ivry, and either mixed with the other water or retained in separate reservoirs. In addition, very large quantities of river water, distributed through a separate system, are used by public authorities for street cleansing, etc., and by factories, and the maximum amount that can be removed from the rivers is being approached. There have been proposals therefore to seek further supplies from the water-bearing beds in the valley of the Loire, 200 km. south of Paris, which, it has been estimated, could yield 1 million cu.m. a day. It is probable, however, that the cost of the water thus obtained would be greater than that of water from the Seine after it has been filtered and pumped up to the reservoirs. Technical improvements have now made it possible to use artesian water in the outer districts: e.g. the artesian well sunk at Aulnay-sous-Bois in 1933 to a depth of 831 m. yields 5,000 cu.m. a day for the north-western districts.

INNER PARIS

Inner Paris: Population Changes since 1841

The slowing up of the rate of increase and eventual decline in the population of Paris was accompanied by a very rapid growth in the surrounding region, but before dealing with Greater Paris something

Fig. 30

Fig. 31

Fig. 30. The decline of population in the centre of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The decline in the central districts has been most marked in those which lie to the north of the river, particularly in the arrondissement of La Bourse and in the quartier of Les Halles.

Fig. 31. The growth of population in the outer districts of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The outer arrondissements of the city have increased considerably in population; more especially those which lie to the south. These areas have a number of light industries, and they also contain the homes of large numbers of the people who work in the heart of the city, many of whom have been displaced from the centre in recent decades. Outstanding among the districts of rapid increase are Clignancourt to the north, Buttes Chaumont and Menilmontant to the east, Vaugirard and Petit Montrouge to the south, and Auteuil and Passy to the south-west.

should be said of the distribution of population within the city limits. The city, that is, the area within the *enceinte* of 1841, plus the narrow military zone around it, the Bois de Boulogne, and the Bois de Vincennes, has an area of approximately 78 sq. km. In comparison with other great cities, this is relatively small, and the average density of population (37,000 per sq. km. in 1931) is consequently high. The administrative County of London, for example, has an area almost four times as great. Towards the end of the century, in 1896, the

corresponding figure was 32,000, so that the increase in density between 1896 and 1931 was 15 %. But this increase was not uniform over the whole city.

Two tendencies have been at work. With the continually increasing scale of operations, the heavier industries which had at first tended to concentrate in the northern quarters of the city began to move outwards into the open country, where ample and cheap sites, well placed for river and rail communications, were available. As a result, the Paris region became one of the most important in France for chemical, textile, and engineering works, and in 1931, 20% of French skilled workers were resident in the departments of Seine and Seine-et-Oise. Another tendency has been the so-called ⁱ 'flight from the centre'. The increasing demand for sites for administrative and commercial offices, banks, large stores, etc. in the centre has led to a rise in land values, and the consequent demolition of old residential property. Moreover, the improved facilities for travel to and from the suburbs have enabled city workers to live at a distance from their work. The insanitary condition of the former densely peopled quarters has also led the municipality to demolish properties and to move the inhabitants to new quarters on the edge of the city. The result of these developments has therefore been to reduce considerably the density of the resident population in the centre of the city, to increase that of the quarters on the periphery, and to bring into existence in the Greater Paris region large industrial and dormitory towns (Figs. 31-33).

Inner Paris: Distribution of Population

Comparing the distributions of 1896 and 1931, it is apparent that Paris can be regarded as composed approximately of three zones with individual characteristics, in which varying tendencies are visible.

The centre of the city, comprising the first seven arrondissements, covers the three historic components of *cite*, *ville*, and *universite*. The most densely populated of these arrondissements is the Temple, with over 50,000 inhabitants per sq. km., followed by L'Hotel de Ville and La Bourse, all on the north bank with 25,000-50,000 per sq. km. These constitute the financial and commercial district, with subsidiary activities such as newspaper production, and have all declined in resident population. This is particularly noticeable in La Bourse, where three of the quarters decreased by more than 35 % between 1896 and 1931. It is significant, as showing the piecemeal nature of this outward movement, that the fourth quarter remains one of the most densely

populated in the city, Bonne-Nouvelle with 101,500 per sq. km., and that the St Gervais quarter of the Hotel de Ville had in 1931 the exceptionally high density of 106,900 per sq. km. The fourth of these arrondissements on the north bank is the Louvre, with a lower density of 10,000-25,000 per sq. km. This includes the central markets (Les Halles), and also an area lying between the Champs-Elysees and L'Opera, which is the centre of 'haute couture', i.e. the production of 'Paris fashions'. The reason for this localization probably lies in the former focusing of court life around the Louvre and the Tuileries. The more popular 'grands magasins' lie between this point and the commercial area. Decline in population has also been very marked here, that of the quarter of the Halles having exceeded 50%. This area is also the home of highly skilled craftsmen, working on a small scale, e.g. costumiers, tailors, gold- and silversmiths, jewellers, and leather workers, who supply the demand for luxury articles.

The portion of the central area south of the river comprises the Pantheon, Luxembourg, and Palais Bourbon. The first two, corresponding to the University and 'quartier latin', had densities of 25,000-50,000 per sq. km.; the third, containing the homes of the aristocratic families of the Faubourg St Germain, of the diplomats in the shadow of the Quai d'Orsay, and of retired officials, is less heavily populated (10,000-25,000 per sq. km.).

The second zone, on the north bank, includes the arrondissements of L'Opera, L'Enclos-St Laurent, and Popincourt. This is the area of the Gares St Lazare, du Nord, and de l'Est, of the Canal St Martin, and consequently of commercial and manufacturing activity. Thus L'Opera and Popincourt were two of the three arrondissements which still retained in 1931 densities greater than 50,000 per sq. km. The quartier Rochechouart of L'Opera had the high density of 90,300 per sq. km., and was the sole area in this zone which increased during this period. The decline elsewhere was largely due to the spread of business houses and luxury shops in this direction from the centre: as a result, one district adjacent to La Bourse, the 'quartier de la Chaussee d'Antin', had decreased by more than 50%. The decline was less marked in Popincourt, which is largely a district of workers' tenements, with a large foreign element.

The third zone is that of the outer ring of arrondissements, mainly industrial and working-class areas, e.g. Batignolles, Montmartre, Chaumont, and Vaugirard, with a density in general between 25,000 and 50,000 per sq. km. This ring is broken at one point in the south-west by wealthier residential districts on the heights of Passy. Save

in a few minor districts, the population of this zone increased markedly since 1896. High increases of over 150% occurred in the manufacturing area of Vaugirard, and in Passy; several other quartiers increased by 65-120%. Though not the scene of heavy industries

Fig. 32. The density of population in the department of the Seine, 1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 20 (Paris, 1934).

In the city itself the greatest densities are found to the north of the Seine. In the remainder of the department the principal area of high density lies to the north-west on both sides of the Seine—at Neuilly, Clichy, Puteaux, Courbevoie and Colombes. This distribution largely reflects the distribution of industry in Greater Paris. B, Bois de Boulogne; V, Bois de Vincennes.

similar to those of Greater Paris, these exterior arrondissements have a variety of industries, such as the furniture factories of the Faubourg St Antoine (Batignolles), the boot factories of Belleville, and the light metal works of Charonne, apart from those more directly associated with the railways. These areas are also the homes of those displaced from the centre who work daily in the city and the west.

GREATER PARIS

Growth of Population

The boundaries which should be assigned to Greater Paris are not easy to determine precisely. During discussions in 1932 on future

Fig. 33. The growth of population in outer Paris, i.e. the department of the Seine outside the city limits, 1876-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 22 (Paris, 1934).

While the increase has been fairly general, it has been most marked to the north and north-east, and in some areas to the south. It will be noted that these areas lie mostly away from the city limits, for by 1876 the communes immediately adjoining Paris had already begun to experience a growth of population spreading outward from the city. These more remote communes, such as Gennevilliers and Colombes to the north-west, La Corneuve, Le Bourget, Drancy, Aubervilliers, Pantin, Bobigny and Villemomble to the north-east, and Gentilly, Villejuif and Sceaux to the south, had very small populations in 1876, and with the spread of industry in recent decades their growth has appeared all the more striking.

growth it was declared to consist of the department of the Seine, those communes of Seine-et-Oise and Seine-et-Marne within a radius of 35 km. of Paris, and a large proportion of L'Oise, forming an area

Fig. 34

of approximately 5,000 sq. km. with a population of 6,300,000. This deliberately included areas not then dominated by Paris: but whatever the exact boundaries, there is no doubt that the whole of the department of the Seine falls within Greater Paris, and recent censuses show how rapid has been the growth of its population. In 1881 the department, excluding Paris, had 530,000 inhabitants: this figure, by 1901, had nearly doubled (956,000), and trebled by 1921 (1,506,000); by 1936 it was 2,133,000, comparable with that of the city itself, with an average density of approximately 5,300 per sq. km. (Figs. 32, 33).

Development in these outer regions has spread along the lines of communications, absorbing long-established towns, and generally repeating the characteristics of the city's quarters thus extended—industrial areas on the lower, more accessible land, and residential suburbs on the higher. Four industrial areas are conspicuous : * (1) the north and north-eastern, comprising St Denis, St Ouen, Aubervilliers, and Pantin; (2) the west and north-western, spread along the winding valley of the lower Seine (Fig. 34); (3) the south-eastern, in the upper Seine valley as far as Choisy and extending west to the valley of the Bievre; and (4) the south and south-western, adjoining the city limits in the Gentilly, Vanves, and Arcueil areas, and extending westwards to Issy-les-Moulineaux.

North and North-eastern Industrial Suburbs. The first of these is of considerable importance. The basis of its development has been the St Denis canal, which, via the Canal de TOurcq, brings Pantin on the east within the area. The important industries of St Denis produce locomotives and wagons, engineering and electrical equipment, acids, fertilizers, soaps, etc., and along the Seine ships and barges are built. St Ouen to the south has a number of very diversified industries, generally of a lighter character—copper and aluminium

* For details of industry, see pp. 177-9.

Fig. 34. The industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The line of the 1841-5 fortifications is represented by the circular line of railway, except to the east where it is marked by a belt devoid of factories. Thus to the north, north-west and south-west most of the factories lie outside the city limits, while to the east and south they lie more within them. It is clear that the location of the larger factories is much more closely related to the river and to the railways than to the canals. The Port de Gennevilliers is a barge port of recent construction, in which the two existing docks will be followed by others, the whole system being designed to serve the growing industries of Colombes, Gennevilliers and Argenteuil.

goods, tinned foods, furniture and pianos, gloves from skins. The industries of Aubervilliers, La Courneuve, and Pantin are predominantly chemical, ranging from oil refining to perfumes and toilet articles, while the by-products of the Villette slaughterhouses are used for the manufacture of tallow, margarine and leather. In these districts the available labour has attracted many minor factories,

Fig. 35. The metal industries of Greater Paris, 1939

These include mechanical and constructional engineering and a variety of metal manufactures. The majority of these factories lie to the east and south.

producing, for example, glass and pottery at St Denis, and sewing cotton and tobacco at Pantin. These five communes form a block of over 240,000 inhabitants, which increased between 1921 and 1936 by approximately 15%, despite a marked decline in the depression following 1931. This manufacturing area is spreading north-eastwards towards the rail and air centre of Le Bourget, competing for the available land with the builders of housing estates, who have been particularly active around Drancy (Figs. 28, 35).

West and North-western Industrial Suburbs. The second great industrial group is in the west and north-west, established along the valley of the Seine. Immediately west of Paris is the centre of the French motor and aircraft industries, with the Citroen works at Grenelle and the Renault at Boulogne-Billancourt (Plate II). Here

Fig. 36. The electrical, automobile and aircraft industries of Greater Paris, 1939 Based on (1) *Carte Industrielle de la Région Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The concentration of these industries to the north-west and south-west is clear. Figs. 35 and 36 are complementary, and show between them all the metal-using industries. Fig. 35 shows mainly old-established industries; Fig. 36 shows newer industries.

expansion has been rapid, the population of the latter commune having increased from 68,000 in 1921 to 97,000 in 1936. Farther downstream, on both sides of the valley, extends a string of industrial concentrations combining the engineering and manufacturing activities of their neighbours to the north and south: Suresnes, Puteaux (armaments), Courbevoie, Levallois-Perret (motors and aircraft), Clichy (gas works and oil refineries along the river), and Asnteres (chemicals

and foodstuffs). The population of this zone exceeds 380,000, having increased by approximately 20 % between 1921 and 1936. Expansion has progressed in the loop of the Seine towards Argenteuil, notably around Gennevilliers, where there is a large electric power station fed by water- and rail-borne coal. Interlaced with these and standing on the higher ground are residential suburbs, e.g. Neuilly, Nanterre and Colombes (Fig. 36).

South-eastern Industrial Suburbs. The industrial areas are repeated on a somewhat smaller scale in the south-east along the Seine valley through Ivry and Vitry, where there are large power stations and gasworks. Vitry, however, still continues to grow flowers for the city markets, whilst Choisy manufactures linoleum, paper and china. Here live a population of some 120,000.

South and South-western Industrial Suburbs. Another industrial belt extends to the west, skirting the city limits as far as the Seine; its features are the tanneries and laundries in the valley of the Bievre around Gentilly which perpetuate the early use made of its waters, and Issy-les-Moulineaux, with its power stations, munition and cement works, breweries, and tobacco factories. This sector has a population of over 200,000. From its western end a series of small towns continue southwards over the broken plateau, and house thousands who work daily in Paris; these towns, interspersed with market gardens, carry the boundaries of Greater Paris beyond Sceaux. The recent electrification of the railway line serving this area may be expected to stimulate the further development of dormitory estates.*

Eastern Residential Suburbs. In this circuit of Paris one sector has so far been omitted, the eastern, which has become the predominantly residential area of the outskirts, beyond the factories along the eastern border of the city. Extending over the gentle and formerly wooded hills north of the Marne as far as the boundary of the department are numerous residential towns such as Vincennes, Montreuil, and Fontenay-sous-Bois, with islands of orchards, vegetable and flower gardens, scarcely touched by industrial development. Nearly a quarter of a million people have their homes in this sector of Greater Paris. Similar expansion has taken place along the valley of the Marne, the tide of building progressing from one loop of the river to the next as far as Nogent. The peninsula between the Seine and the Marne is occupied by the working-class suburb around Alfortville comprising some 75,000 inhabitants. In the first great loop of the Marne is the garden city of St Maur (57,000); in the next Champigny (27,500),

* See vol. iv, chapter iv, of this Handbook.

and again in the next Nogent and Le Perreux (together 45,000), developments all consequent on the breaking up of large estates towards the end of the last century. Market gardening is still carried on to some extent, but except around Alfortville and Maisons-Alfort there has so far been little industrial development.

Regional Planning

This development of the Paris region has been haphazard and unco-ordinated. Factories and housing estates are intermingled: the new quarters of the expanding towns are often unprovided with adequate roads, drainage, or water supply: valuable agricultural land has been built over: and natural amenities have been destroyed. This has resulted from the lack of a central authority, the constituent communes being largely independent and without the means to develop in an orderly way. In 1932 a law prescribing a 'projet d'aménagement' for the whole region was promulgated. A general directing plan was drawn up and presented in 1934, with which the local schemes were to conform. It covered the lay-out of the main roads, open spaces, the use of the land and the regulation of buildings, public services, and the protection of sites. The scheme for communications provided for five radial motor roads in conjunction with an outer ring at a distance of some 20 km. from the centre.* For several reasons, among which the conflict of local interests is not the least important, progress with the scheme has been slow.

Attempts have also been made from time to time to check the continued concentration of industries, particularly aircraft works, in the Paris region, as this was considered to be strategically dangerous. In 1931 a fund was instituted to assist the removal, if required by the Air Ministry, of aircraft factories to a particular zone, and the scope of this measure was afterwards enlarged. Three years later the Departments of National Defence ruled that works thereafter established in the region should in general be excluded from their supply lists, and in 1938 official approval was required for the siting of new munition factories. It does not appear that this movement had made any considerable progress before the outbreak of war, one obstacle being the disinclination of the workers to migrate with the factories.

BIBLIOGRAPHICAL NOTE

(1) An account of the geographical factors important in the development of Paris will be found in the following articles and books:

See vol. 1, p. 249, of this Handbook. A detailed map showing the density of population in Paris and the Paris region in 1931 can be found in the *Atlas de France*, Plate 72 (Paris, n.d.).

Chapter III

AGRICULTURE

Introduction: Wheat: Other Cereals: Root Crops: Minor Crops: Wine and other Beverages: Market Gardening: Livestock: Working Population: Land Tenure: Legislation: Forests: The Vichy Regime: Bibliographical Note

INTRODUCTION

France is a country highly favoured by nature from the point of view of agricultural production. Of its working population, 35% are engaged in agriculture, and the urban areas are to a great extent fed by home-grown food. A map showing density of population exhibits a remarkable continuity in distribution; only in the highest parts of the Alps and the Cevennes and on the sandy forested stretches of the Landes are there any considerable empty areas. Cultivation penetrates far into the highlands of the Alps, the Vosges and the Jura, following the terraces of the river valleys; it covers the lower platforms of the Central Massif; it renders return, however meagre, even to the dense population of the poor acid soils of Armor in Brittany. If pastoral pursuits and forestry are included, there is hardly a corner of the country left unproductive.

Climate, soil and relief have greatly contributed to this high degree of land utilization, and to these factors must be added the late development of French industry. Both climatic and soil conditions present considerable variety. Exposure to Atlantic winds precludes the harsh winter conditions of more northerly and more continental areas, so that the sheltered bays of the Breton coasts are able to grow early vegetables for export. The extension southwards to Mediterranean shores and the protection afforded by the Cevennes and the Alps against northerly winds give to France a share in Mediterranean products, and have made possible the large-scale cultivation of *pruneurs*; yet, except in the Rhone delta and the eastern-facing valleys of the Pyrenees, the summer drought is not sufficiently prolonged to make cultivation entirely dependent upon irrigation. In the east of the country there is an approximation to continental conditions of agriculture, with the cultivation of maize, hops and tobacco in the lowlands. Finally, the ample development of mountain and plateau in the south and south-east with Atlantic-facing slopes is the basis for pastoral and forest industries.

A generalized view of the soils of France is difficult, partly because of the variety of soil types within a small area, partly because centuries of intensive cultivation, marked even by the transference of soil from one locality to another in barges, has made the present distribution in some areas almost artificial. Despite this, certain predominant soil groups are apparent. The most important contrast is between mountain and lowland soils. The former vary from the rich soils of the volcanic districts of the Central Massif through the moderately fertile calcareous soils of the Jura to complete poverty in parts of the Alps and Pyrenees. Acid soils, too inaccessible for economic liming, must be content to produce such 'poor man's crops' as rye and buckwheat. The lowland soils are equally variable—from the poor sands of the Landes and the sands underlain by clay of the Sologne to the rich alluvial deposits in the river valleys. The prevalence of limestone and chalk ensures large areas of warm, well-drained land; the distribution of *Union* on these high, limestone plains of northern France provides a fairly heavy, loamy soil, suitable for wheat, sugar beet and other root crops. Sunny, south-facing slopes on well-drained limy or gravelly soils produce vines as far north as the river Aisne (Fig. 46). Alluvial river terraces, especially when covered with loessic deposits, are intensively cultivated throughout the land. Ill-drained valley bottoms, moorland, coastal marshes and mountain shoulders or 'alps' provide meadow and permanent pasture.

Upon these diverse soils the intensive cultivation of the small farmer has in many places developed a specialized agriculture, but taking the country as a whole, the yield per hectare is a moderate one for western Europe. It is considerably lower than the yield in such countries of intensive peasant farming as Holland, Belgium and Denmark, and also appreciably lower than the yield in the United Kingdom and Germany, as shown in the following table:

	Yield (quintals per hectare) 1933-7 average			No. of livestock per 100 ha. of cultivated land, permanent meadow and pasture, 1937	
	Wheat	Barley	Oats	Cattle	Pigs
France	15'3	14'3	14'0	45	20
United Kingdom	22'8	20'6	20'4	48	36
Germany	22'2	20'9	19'9	71	83
Belgium	26'5	26'1	26'5	88	52
Holland	29'6	28'7	23'9	109	71
Denmark	31'3	28'4	25'9	93	111

From *Annuaire Statistique*, 1938 (Paris, 1939), which gives *Tableaux Retrospectifs* for a number of countries.

A comparison of the densities of "livestock likewise reflects the different agrarian economies of these countries. Figs. 37 and 38 show the percentages of arable land and grassland respectively in each department in 1938. The proportion of the total agricultural land devoted to each type of farming activity is shown in Fig. 39. The adjoining table summarizes the agricultural production of France.

Summary of Agricultural Statistics, 1938

	Hectares	Quintals (except where otherwise stated)
Cereals:		
Wheat	5,050,199	98,010,002
Oats	3,245,257	54,574,380
Barley	759,223	12,907,804
Buckwheat	261,366	2,422,894
Rye	631,096	8,111,314
Maize	340,290	5,786,067
Millet	9,212	88,266
Other products:		
Potatoes: New	113,235	9,266,727
Others	1,425,000	173,145,000
Sugar beet	319,000	79,800,000
Fodder beet	976,000	382,600,000
Flax	38,000	238,000
Tobacco	18,100	33,166,280 kg.
Hemp	3,802	41,873
Grapes	1,567,000	60,300,000 hl.
Hops	1,600	21,3'00
Cider	—	34,600,000 hl.
Market gardening	437,000	—
Olives	—	333,000
Livestock:	Numbers	
Cattle	15,622,000	
Sheep	9,872,000	
Pigs	7,126,000	
Horses	2,692,000	
Milk	133,241,000 hi.	

The source of this and of other tables in this chapter (except where otherwise stated) was *Statistique Agricole Annuelle* (Paris, latest edition refers to 1938).

WHEAT

In few parts of France are to be found the cool damp conditions that preclude the successful growing of wheat, as in western Britain, and as a result the area under wheat is half that under all cereals. The age-long localization of grain varieties enables most soils that are cultivated with intensive assiduity to be used.

The more important wheatlands (those with an average departmental production of over 2½ million quintals per annum) are situated in the departments to the north and east of Paris (Fig. 40). These areas

Plates 12, 13. Farms in the Bourbonnais

The Bourbonnais lies on the northern edge of the Central Massif between the rivers Cher and Allier. Plate 12 (above) shows the large establishment typical of a former social system; the fifteenth-century *Maison du Maître* lies adjacent to the dwellings of the *metayers* on the left. It is more common for the former to have a separate existence as a chateau. Plate 13 (below) is of a small farm more typical of modern French agriculture.

mainly comprise low limestone plateaux providing a well-drained subsoil covered with fertile surface loams. Wheat is also cultivated intensively on the alluvial terraces of the Seine and its tributaries (Plate 15). Districts with over 15.5 quintals per hectare stretch from the Seine valley to the Belgian frontier. Other areas of high yield are Languedoc, especially on the lava soils, the basins of the middle Rhone, the lower

Fig. 39. Utilization of agricultural land, 1938

Charente region in northern Aquitaine, and the upper valleys of the Mayenne and the Sarthe. Next come the coastal plains of western Brittany, Normandy, the Alsatian terrace lands, and the terraces of the lower valleys of the Alps and Pyrenees. The mountainous regions, together with the coastal regions of the Landes and the Mediterranean, are least important, although even there small areas of relatively level land are utilized (Plate 19).

The area under wheat decreased towards the end of last century as less favourable lands went out of cultivation. Between 1914 and 1918 the decline was rapid due to the ravaging of the north-east by war. Since 1919, the gradual recovery of these areas has been balanced by

Fig. 40. Production of wheat in quintals per 100 ha. of each department, 1938

a steady decline in the south and in other districts such as Normandy, where wheat occupied in 1933 only two-thirds as much land as in 1913. The latter decrease was due in part to the competition of dairy farming. As a result, the total area under wheat has remained relatively constant since 1923 but with a slight tendency towards decline. There has been some restriction in wheat growing as part of a general policy

of avoiding over-production. In 1933, producers were put on an area quota based upon an average of the three preceding years. The yield per hectare, although obviously masked by good or bad harvests, has

Fig. 41. Production of cereals, 1924-38

risen steadily, partly because less favourable lands have gone out of cultivation and partly because of an increased use of fertilizers (chiefly of superphosphates, potash, basic slag, etc.). Thus, although the area under wheat has declined by about 20 % since 1913, the increased yield has resulted in six harvests (those of 1925, 1929, 1932, 1933, 1934 and

Plate 15. Arable farming in Beauce

A photograph taken east of Chateaudun, showing the broad, flat, almost treeless expanse of intensively cultivated land.

Plate 16. Sheep-folding in Beauce

As in Britain, sheep folded on stubble or roots are an essential part of the arable farming economy of limestone regions such as this.

Plate 17. The Champagne Plain

View eastwards from Mt Aime, about 30 km. west of Chalons-sur-Marne. The level or gently undulating plain is between 100 and 150 m. above sea level. Hedgeless cultivated fields alternate with strips and rectangular blocks of planted pines.

Plate 18. Grain elevator near Castelnaudary (Aquitaine)

France is largely self-supporting in grain, and in consequence large quantities are stored at inland towns and not necessarily at the ports, as in Britain. The majority of elevators are owned by co-operative societies, in this case by the *Greniers reunis des agriculteurs Lauraguais*.

Maize yielded 5¾ million quintals in 1938, and it is important only in the south-west where conditions are moist, warm and virtually frost free. It is grown mainly as a fodder crop, and large supplementary quantities have to be imported. Small quantities are cultivated throughout eastern France—a reflexion of the increasing incidence of summer rainfall.

Millet. Only 88,000 quintals were produced in 1938, and of this Vaucluse, a department consisting largely of the Fore-Alpine limestone plateaux, grew almost one-half (41,000 quintals).

ROOT CROPS

Potatoes. Nearly 3 million hectares of ground are under roots and kindred crops, and almost half of that total (i.e. 44%) is occupied by potatoes. They are grown very widely for local consumption, and as the total crop exceeds the requirements for human consumption much of it is fed to pigs or used in the manufacture of alcohol and starch. Two districts specialize in the crop, namely, Brittany, which produces new potatoes, and the area around Strasbourg. Up to 1932, France exported a large amount of early potatoes, especially to Great Britain, but the extension of the Colorado beetle into Brittany has considerably reduced this trade.

Beet. Both fodder beet and sugar beet are grown to a considerable extent in France, roughly in the proportion of four to one respectively. Fodder beet is grown widely in the northern plains, chiefly for the fattening of stall-fed animals. Sugar beet is localized in the extreme north and around Paris (Fig. 43). The beet is grown on large farms in conjunction with wheat, both crops benefiting by the rotation.

Although many sugar refineries were destroyed during the war of 1914-18, the general rise in the standard of living since then has almost doubled the consumption per capita of sugar; the number of refineries is still below the 1914 total, but their output is much greater. The total number of refineries in France is 111, and of these seventy are situated in northern departments. The changes in this area are summarized below:

Refineries in Operation

	1912-13	1920-23	1928	1938
Nord	40	13	13	13
Pas de Calais	24	8	12	12
Somme	33	7	9	14
Oise	20	16	18	18
Aisne	51	11	13	13
Total for five northern departments	168	55	65	70

Fig. 44. Production of wine in hectolitres per 100 ha. of each department, 1938

At the same time as home production increased, sugar imports from the colonies increased almost fourfold compared with pre-1914 totals. As sugar stocks accumulated and the price of beet fell, an agreement was negotiated in 1931 between growers and refineries whereby the price of beet was fixed relatively to the price of sugar, and the refineries accepted voluntary quotas. At the same time the French colonies undertook to limit their shipments to 13 % of the home-produced total. Thus the industry achieved a certain equilibrium without state control, and the area under cultivation has fluctuated but little.

In addition to the utilization of the beet crop for sugar-refining, large quantities are sent to distilleries for the manufacture of alcohol.

MINOR CROPS (Fig. 45)

Flax is grown in the north-eastern departments in the Scarpe and Lys valleys, where a multitude of watercourses makes flax-retting easy. It does not, however, occupy more than 1½ % of the total arable land of the two most important producing departments of Seine-Inferieure and Nord. After a revival which reached a maximum in 1929 (79 % higher than in 1913), economic depression hit the industry, and in 1931 21,000 ha., almost two-thirds, went out of cultivation. The crop has been revived in recent years by a substantial state subsidy and has shown a striking increase since the lowest yield in 1932. In 1938, it was again above the 1913 total.

Tobacco is grown under state regulations and with a subsidy to a small but increasing extent in the south-west (Plate 20), in the two Rhine departments, and to a much less extent in the north-eastern departments and in those of Savoie, Isere and Drome. In Alsace it forms one of the two main crops of the reclaimed Rhine flood-plain—hops being the other.

Hemp is grown to a very small extent by state subsidy in the Loire valley, but in no department does it exceed more than 0.5 % of the arable land

WINE AND OTHER BEVERAGES

Production. France is the most important wine-producing country in the world, although Italy has a greater area under vineyards. But the French yield per hectare (401.) is almost twice that of Italy (22'11. per ha.), and in the production of fine wines France stands alone.

The vine, while not unduly exacting, as it is able to withstand periods of frost, requires a moderate rainfall in spring and early summer with strong continuous sunshine during the late summer and autumn. It grows very widely (Figs. 44, 46) on most types of soil, preferring well-drained stony or gravel soils. The effective northern limit of

Fig. 45. Production of flax, hemp and tobacco, 1924-38

the vine is shown on Fig. 46. The bleak uplands of the Central Massif are obviously not suitable, while the southern Landes and western Pyrenees are subject to warm moist air which encourages mildew. It is interesting to note that the marginal areas of the north, where exceptional and intensive care is necessary, produce some of the best vintages.

Plate 19. Grain harvest in upper Dauphine

Almost every patch of level land in the mountains, snow-covered in winter, is utilized in summer to produce crops of hay, grain or potatoes.

Plate 20. Tobacco cultivation near Beynac (Dordogne)

The rolling limestone country of eastern Aquitaine yields good soils on well-drained slopes. Most of the small farms have a field of tobacco (a carefully cultivated and remunerative crop) and a number of fruit trees.

Plate 21. A Champagne cave at Reims

Storage at even temperature in caves hollowed out of the chalk assists the maturing of the

Vine growing is mainly in the hands of small-scale cultivators, as a vineyard in full bearing fetches a high price per hectare. In 1924, 82 % of the 11 million growers who declared their output had holdings smaller than 2 ha. The remaining large holdings are found chiefly in the Garonne-Dordogne area, where famous Chateau vintages are

Fig. 46. Main wine-producing centres

Based on *Guide Michelin*, p. 28 (Clermont-Ferrand, 1939).

produced, a few in the Loire valley, and a very small number in the Champagne district. Many of the vintage wines such as those of Burgundy are grown by small cultivators and blended by large merchant firms.

Normally over half of the French output comes from the Midi. The grape grown is largely the *petits vins* cultivated on an extensive scale, and it provides the cheap *vin ordinaire* so widely consumed within

the country. The centres of the Midi wine industry are at Beziers, Nîmes, Perpignan and Montpellier (Plate 21).

The second great wine-producing area is in the south-west, and follows closely the valleys of the rivers Garonne, Dordogne and Charente, with Bordeaux as headquarters. About a quarter of the French total comes from here. Four distinct localities produce the high-grade vintage wines. The Medoc region yields fine clarets; south of Bordeaux is the Graves area; on the hills north of the Dordogne lies St Emilion; finally, the much smaller Sauternes district lies on both sides of the Ciron, a tributary of the Garonne. In south-western France are the brandy-distilling areas of Cognac, including the greater part of the departments of Charente and Charente-Inferieure, and the less important Armagnac district in the department of Gers, south of the Garonne.

Another group of wines are the Burgundies, which come from lower Burgundy (the Chablis district), the Maconnais and the Beaujolais; the most important area is the Cote d'Or, between Dijon and Chagny. Here the soil and climate are exceptionally favourable, and owing to scattered villages and the large number of small growers the wines differ widely. About one-twelfth of the French total is produced in this district (Plate 23).

The Champagne area lies in the department of Marne. The four main districts are (1) the slopes of the limestone hills known as the Montagne de Reims; (2) the Cote des Blancs south of the river; (3) the Marne valley itself; (4) and, finally, the lower slopes of the chalk escarpment in the extreme east of the department. The wine, which is essentially an artificial product blended from the output of all of these districts, is the result of careful culture, pressing, fermenting, maturing and blending. The production, however, is inconstant and constitutes a very small proportion of the French total, averaging only about a quarter of a million hectolitres (Plate 21), although in a 'good vintage' year the value is considerable.

Another important wine-producing district is in the Loire valley. The chief areas are in Anjou and Touraine, which yield such famous wines as Vouvray and Saumur; the coastal departments produce white wines such as Muscadet, and the rest of the valley produces large quantities of *vin ordinaire*. The production averages about 5 million hl., about one-twelfth of the French total.

Alsace-Lorraine is also a small producer of wine. The vines are grown on the lower slopes of the Vosges and in the eastern valleys, sheltered from winds and with sufficient sunshine (Plate 24). Much

of the wine is of ordinary quality, but such white wines as Muscatel, Riesling and Turckheim are exported.

Finally, in the Jura a number of notable wines, such as Ch&teau-Chalon and Arbois, together with much *vin ordinaire*, are produced.

Output. The area under vines grew steadily to a maximum of 2,447,000 ha. in 1874; the production of wine for market reached a total of 83.8 million hl. in the following year, a figure which has never again been reached (Fig. 47). Only about 3 % of this total was exported, but in value it was a much greater proportion of the whole. By 1879, production had sunk to 25.8 million hl.; this startling decline was due to the ravages of the *Phylloxera*, an insect native to the United States which had been introduced into Europe between 1858 and 1863 with American vine stocks. The insect multiplied at an enormous rate and attacked the roots of the highly susceptible European stocks, thus tapping the flow of sap and destroying the

Fig. 47. Production of wine and cider, 1830-1938

vine. Over a million hectares of vineyards were destroyed in France, and the financial loss is estimated to have been much greater than the indemnity paid to Germany after the Franco-Prussian War. The pest was overcome by (1) the large-scale introduction of a relatively immune American stock upon which the French vine was grafted, (2) the injection of carbon bisulphide into the ground, and (3) winter flooding where practicable. But the quality of subsequent vintages suffered, and in many localities vine growing was permanently abandoned. By 1911, an area of some 1½ million ha. was under the vine, producing about 45 million hl., and this area has remained relatively stable.

But although the *Phylloxera* was conquered, the wine industry never went back to its previous prosperity. During the years of low production, Spanish, Italian and North African wines made considerable headway. Algeria, being within the French customs territory, rapidly increased its output and sale in France. In addition, the cultivation of the vine in other parts of the world, notably in

South Africa, Australia and South America, caused further decline in French wine exports. South American wines hit especially the export of *vin ordinaire* from Bordeaux to the Latin republics.

The diversion of labour from agriculture during 1914-18 left* the vineyards open to disease, and in 1915 two-thirds of the crop was lost owing to mildew. Since that time the industry has recovered somewhat, but it has been hit by the heavy and increasing English excise duties, by Prohibition in the U.S. between 1920 and 1933, after that by the relatively small import quota allowed by the U.S., and by the general world economic crisis, wherein wine as a luxury product suffered severely.

As wine is the principal drink of the country, it is likely that the total amount produced is very many times that exported. But the home consumption has fallen greatly, owing to the general economic crisis, to unduly high prices, and to the greater adoption of other beverages such as beer and cider. Between 1931 and 1933, many of the great proprietors became bankrupt and their estates were broken up for sale. Since 1933, however, there has been some degree of recovery.

Beer and *cider* are the principal beverages in the areas where the vine cannot be successfully grown, although the first is increasing as a drink generally. *Beer* is produced chiefly in the north and east, *cider* in the north-west. Hops are grown in Alsace and Burgundy, but from the latter area they are sent to the breweries in the Nord and Rhine departments. Both the area under cultivation and the total yield fluctuate considerably. *Cider* is the normal beverage of Brittany and Normandy, and is produced in the apple-growing departments that border the English Channel. The chief feature about the yield is its variability (Fig. 47). Thus the yield in 1938 (34.6 million hi.) was more than twice that of 1937.

MARKET GARDENING

In many parts of France climate and soil, together with intensive skilled labour, have resulted in the localization of special crops. Adjacent markets in large towns have encouraged the large-scale production of 'perishable' commodities which command a good price. With the organized development of fast main-line trains with refrigerator cars (notably by the P.L.M.) and of motor transport, district surpluses have been sent farther afield. Thus Vaucluse and Var are able to send fresh produce to Paris, while a large amount of table fruit,

Plate 22. A vineyard near Narbonne (Aude)

Extensive vineyards in the Midi yield vast quantities of *petits vins*, grown and processed for the production of cheap *vin ordinaire*.

Plate 23. A Burgundy vineyard

The typical unit of production in the wine industry of Burgundy is the *dos*, of relative y small extent, from which the vintage derives its name—in this case Clos-Vougeot. Behind the chateau is the escarpment of the Cote d'Or.

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

Chapter I

GROWTH AND DISTRIBUTION OF POPULATION

Introduction: General Features; Occupation Groups

Distribution of Population: Brittany; The Paris Basin; Northern France; Eastern France; West and South-Western France; The Central Massif; The Pyrenees; The Rhone-Sadne Valley; The Jura; The Alps; The Mediterranean Coastland

Growth of Population: The Balance of Births and Deaths; Immigration; Age Groups; Death-Rates; Birth-Rate, Fertility and Reproduction Rates; Future Trends

Regional Variations in the Growth of Population: Introduction; Analysis of the Movements of Population; Rural Depopulation, Immigration of Foreigners

Rural Settlement: Main Types of Settlement; Geographical and Historical Factors in Settlement; Historical Development

Towns and Cities: Number and Distribution of Towns; Urban Growth; Conurbations

Note on Family Allowances

Bibliographical Note

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	
Commerce:					
Wholesale and retail } trade, banking, etc. }	2,695'4	124	1,5382	1,1572	7,515'4
Entertainment }					
Professions	657'8	3'0	332'6	325'1	
Domestic and personal service	893 4	4'1	1766	7168

Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture doree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loire (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

Fig. 5

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

Fig. 6. The distribution of population in south-western France, 1931

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Al, Albi; Au, Auch; Ba, Bayonne; Bi, Biarritz; Bz, Beziers; Ca, Castres; C, Carcassonne; Dx, Dax; Lo, Lourdes; Mb, Montauban; Ma, Mazamet; Mo, Mont-de-Marsan; Mt, Montpellier; Nr, Narbonne; Pa, Pau; Pm, Pamiers; Pn, Perpignan; Se, Sete; StG, St Gaudens; StJ, St Jean-de-Luz; Ta, Tarbes; To, Toulouse; V, Port-Vendres.

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	-35	546	176

* Including the Saar territory.

(2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	+ 4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2'0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938
0-4	82	6'8	8'1	95	103
5-9	8'4	7'2	7'2	96	10'9
10-14	8'6	7'8	8'0	9'5	11'4

65 +	9'8	8'5	7'6	67	
	100'0	100'0	100'0	100'0	100'0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	252	218	23'3	286	32'6
15-49	48'9	53'4	54'0	52'1	51'5
50 +	25'9	24'7	22'7	19'3	14'9
Women: 15-49	48'2	53'3	54'0	52'3	52'6

Of the total population men represent 48'3%; neglecting the foreigners in France, however, men represent only 47'3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations, 1938-9*, p. 44 (Geneva, 1939).
For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14.6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

	1932	1933	1934	1935	1936	1937	1938
Sweden	14'5	13'7	13'7	13'8	14'2	14'3	14.9

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0.880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1.0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1.0 for the greater part of this century:

Net Reproduction Rates

1908-13	0.930	1	1935	0.866
1920-23	0.977		1936	0.88
1925-27	0.929		1937	0.87
1928-33	0.905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Net Reproduction Rates

Poland:	1931-2	1.25	France:	1935	0.866

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141
Over 10,000 inhabitants	341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30%, Toulouse 17%, and Strasbourg 10%; Nantes (6%) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

*Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas*

Conurbation	Population in 000's	No. of com- munes included	Principal communes
1. Paris	5,500		
2. Marseilles	990	9	Marseilles 914; Aix 43; Aubagne 14
3. Lyons	802	32	Lyons 571; Villeurbanne 81
4. Lille-Roubaix-Tourcoing	731	38	Lille 201; Roubaix 107; Tourcoing 78

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

of paying family allowances encouraged the extension of the system to industry, and the shortage of labour in the years 1918-30 provided further incentive to employers to pay these allowances, in order to secure greater stability of labour by the employment of the largest possible number of married men with children. Another motive for the employers was a belief that allowances helped to withdraw family men from interest in the class struggle. To employees the scheme appeared as a means of raising their standard of living. In 1932, some 245 funds covering 1,850,000 employees, and distributing annually 380 million francs, were in operation, and affiliated to a central organization. As the number of private funds grew in these years, the rate of allowances paid to state, departmental and municipal employees increased. Eventually, in 1932, legislation was effected by which all employers were ultimately to subscribe to 'equalization' funds and to grant allowances for dependent children to all French and foreign wage earners and salaried employees.

In 1933 the number of beneficiaries amounted to 5 millions. The programme was extended to more industries, and in 1936 the system was made applicable to all industries and commercial undertakings employing more than ten people, including multiple branch concerns, while in the same year the law was extended to agriculture. The wide extension of the scheme is shown by the fact that the total payments in 1937 were 1,340 million francs, compared with 872 millions in 1936, and were estimated to reach 1,500 million francs for 1938.

Considerable variations were naturally to be found between different areas, both in the rates paid and the subscriptions levied on employers, owing to local differences in wage levels, cost of living, etc. The table on p. 79 illustrates certain rates.

When the scales were revised in 1938, it was provided that the minimum rates should be fixed by the Minister for Labour on the recommendations of the Higher Family Allowances Commission. The age to which allowances were payable for children, apprenticed or pursuing a course of studies, was raised to 17, but after November 1940, no allowance was to be payable for an only child over 5 years old. The new arrangement came into force in April 1939. ,

Machinery for Payment. Funds for the payment of family allowances are obtained entirely by subscriptions from employers. The charges amount to over 2% of the total wages bill in industry. Beginning in 1918, Equalisation Funds (*Caisses de Compensation*) came to be established as a means of regularizing the financial side. Employers contribute to the appropriate funds according to the

number of people they employ, and each fund then distributes the allowances. The Act of 1932 did not create any special machinery for the administration of family allowances, and the existing funds set up by employers were left untouched. Employers not already affiliated to equalization funds were obliged to subscribe. It is important to notice that in order to prevent employers from reducing their liabilities by employing unmarried staff, subscriptions to the funds (*caisses*) are payable for all workers, whether married or single. In 1938 a national compensation fund was established to make grants to local compensation funds, on which the charges were found to be abnormally high. The national fund, which is to be managed by the *Caisse des Depots et Consignations*, is to obtain its resources from subscriptions paid by all the local compensation funds. Until 1932 the subscriptions paid by employers were all voluntary.

Rates of Family Allowances, francs per month

	One child	Two children	Three children	Four children	Each ad- ditional child
1936: normal rate	30	70	120	200	80
1936: rate for state employees	52	76	157	196	—
1937: rate in Paris	30	80	200	400	200
1938: rate in Paris	60	160	300	500	200
1938: rates in agriculture	15 to 25	30 to 85	67'5 to 200	110 to 320	27'5 to 120
<i>Rates as percentages:</i>					
1938: rate in Paris as per- centage (approx.) of mean wage of 20 skilled trades	4	10	18	30	12
1939: minimum rate at re- vised scales for the whole of France, as percentage of adult male wage earner	5	15	30	45	15

Conclusion. It is probably too early to form a judgement upon the effectiveness of family allowances in retarding the decline of the birth-rate. The widespread application of the system has been in effect for too short a time to permit of statistically sound conclusions being drawn. As to the funds which were privately operated by firms on a considerable scale soon after 1920, such as the Michelin Company's fund for its employees at Clermont-Ferrand, it is held by some authorities that the higher birth-rate occurring among the beneficiaries of the funds represents inconclusive evidence. The employees are not a typical cross-section of the adult population as

a whole, and some of the employees may have migrated to the Michelin works so as to take advantage of the allowances.

While the payments under the schemes add to the income of parents, the addition is considerably less in amount than the increase in the cost of living incurred through-children. It has been estimated that three children add to the income of a lower grade civil servant an amount equal to only half of what they add to his cost of living. Hence it is considered by some that the scale of family allowances is too small to have any real effect upon the population position. At the most they may have resulted in a slight diminution of the rate of decline in the birth-rate. Such a view is only an opinion, and so far real knowledge cannot be arrived at until statistical investigation of the family allowance system has reached a much more advanced stage.

BIBLIOGRAPHICAL NOTE

(1) *The Census*

Vauban made an estimate of the number of inhabitants of France as long ago as 1700, and other estimates were made in 1762 and 1764. The first organized census was carried out in 1800, and in the next year, 1801, began the series of censuses, at intervals of five years, which has since been continued, except for the census of 1871, which was postponed for one year, and the census of 1916, which was not held.

When the census forms have been collected, they are first utilized to determine the figures of *population legale* in each commune, i.e. the numbers of persons having their habitual residence in the commune. The forms are then tabulated by the *Statistique Generale de la France*, and the entries analysed by category. The figures of *population presente* are obtained at this stage, i.e. the population actually present in each commune on the day of the census. In 1939 the later calculations had not been completed; only the figures of *population legale* or resident population have been published. These figures have been used in the foregoing account. The completion of the census was not expected until 1940. (See also p. 375.)

The published volume is *Resultats Statistiques du Recensement general de la population en 1936* (Statistique Generale, Paris, 1938).

Summarized statements appear in *Annuaire Statistique, 1938* (Paris, 1939).

(2) *Growth of Population*

The official account of population changes is given in *Statistique du mouvement de la population*, vol. xvi, 1936, Part 1 (Statistique Generale, Paris, 1938). Part 1 deals with marriages, divorces, births and deaths.

Chapter II

PARIS

The Site: The Growth of the City: Inner Paris: Greater Paris: Bibliographical Note

THE SITE

The successive stages in the expansion of Paris from its nucleus on an island in the Seine are closely related to the physical features of its site, and are still clearly embodied in its plan. After receiving the waters of the Maine, the Seine, cutting through a line of low heights, begins the first of its loops towards the north. On the southern bank it receives a small tributary, the Bievre, which after flowing east and north is deflected eastwards again by a low spur, the Mont Ste-Genevieve (Fig. 27). In general the relief on the south bank is broken and of moderate elevation. This broken relief imposed limitations upon the city's early development to the south, but farther to the west near the Champ de Mars a portion of the flood plain allowed expansion. Off the Mont Ste-Genevieve, in the centre of the river, lay a number of small islands, now reduced to two—lie de la Cite and lie St Louis (Plate 10). These islands, and the numerous side branches which originally characterized this stretch of the river, due perhaps to the decrease in the slope of the bed, formed a complicated pattern, but it happened that a line from the southern height across the present lie de la Cite avoided most of the obstacles.

On the north bank, the relief is in contrast to that of the south. A semicircle of heights leaves the river at Charonne on the east, and runs through Menilmontant, Belleville, Montmartre, and Chaillot, returning to the river at Passy. These heights mark the northern slopes of the Quaternary course of the Seine, the loop of which was much more pronounced than that of the present river (Fig. 27). Probably owing to changes in the course of the Marne, which increased the velocity of the Seine, the latter cut off the extremity of this loop to occupy its present course. Thus the area immediately north of the Seine is a segment of a meander plain, originally sloping not to the Seine, which cut a narrow bed through it, but towards the older course. In the early history of the city this was occupied in its western portion by a stream flowing from Menilmontant, and in its eastern end by an area of marshland, Le Marais.

The north bank therefore afforded ample space for expansion, and the growth of Paris in this direction has been closely related to this abandoned river course. At one period, portions of it were incorporated as a moat forming part of the city's fortifications. At times, too, it has proved a source of anxiety to the city engineers, for the Seine in flood has occasionally attempted to reoccupy its former bed. Thus in the floods of 1910 subsoil penetration by this channel flooded large areas round the Gare St Lazare. The original relief, however, has been largely hidden by drainage, by newly-made ground, and by buildings. It is important to note also that the northern ring of heights is not continuous: Montmartre is isolated by gaps to east and west, the former being especially important as it affords an easy line of communication northwards.

The significant features of the site therefore are the approach of the southern hills to the river, the islands in the river bed reducing the difficulty of bridging, the open plain on the north bank, and the breeches in the northern heights. The three main areas—southern heights, islands, and northern plain—have persisted from early days as subdivisions with distinct characteristics associated respectively with Universite, Cite, and Ville.

THE GROWTH OF THE CITY

The Early Medieval City

Before the Roman occupation of Gaul, the Ile de la Cite was the site of a settlement, Lutetia, the centre of a Gaulish tribe, the Parisii. By this time the Seine had been bridged and the island was close to an intersection of routes, a south-to-north land route and an east-to-west river way. Roman observers remarked upon the busy boat traffic on the river. Under Roman administration the principal section of the town was laid out on the southern bank, on the slopes of the Mont Ste-Genevieve. A Roman road from Chartres ran northwards across the lie de la Cite and up through the Montmartre-Belleville gap; on the north bank it was joined by another road descending the valley westwards from Melun, and it was around this junction that commerce was increasingly to centre.

During the first centuries of the Middle Ages however progress was slow. In the disturbed times following the Roman withdrawal and the Frankish advance, when the Roman town on the south bank was destroyed, settlement was chiefly confined to the island with two bridgeheads north and south of the river. Under the Merovingians,

in the fifth and sixth centuries, order was re-established, and with the expanding influence of the Church the elements of civilized life gradually returned. During the reign of Clovis, the basilica of SS. Peter and Paul was built on the southern quarter, and other churches soon followed (St Benoit, St Severin). Settlement on the outskirts was encouraged by ecclesiastical foundations, the abbey of St Germain TAuxerrois on the north bank, and of St Germain des Pres on a former left bank island below the city limits. The surrounding forests were gradually cleared during the ninth century, and with the revival of trade the value of the position of Paris became recognized, by none more clearly than the early rulers of the House of Capet. Indeed, it was their great achievement to establish Paris as the undisputed capital of France. By their efforts the advance of the Norsemen was stayed at the city walls after a siege during which the southern quarter was again destroyed, and their royal duchy, extending north and south of the Seine and conveniently linked by Paris, was welded together to become the foundation of the kingdom of France.*

It was to the centralizing policy of the French monarchy more than to any combination of geographical factors that the city's predominance and extraordinary growth were due. As the seat of the central government, the courts of law, and the great university of the Middle Ages, Paris drew to itself, with increasing attractive power, first the professions and trades necessary to sustain their needs, and later an industrial population to meet the demand for goods as close to the market as possible. Thus the development of Paris has been from an administrative centre to a great commercial market, and finally to an industrial concentration. The development of a planned system of roads, of canals, and of railways merely tightened the hold of Paris on the country.

The effect of this Capetian centralizing policy was soon visible in the development of the city, which during the twelfth century assumed its characteristic tripartite form. The *lie de la Cite* was the centre of royal and ecclesiastical administration. In the middle of the century the building of the new cathedral of Notre Dame was begun, and the church schools formerly grouped around it moved across to the south bank where, around the theological college founded by Robert de Sorbon in 1253, the University and its quarter crystallized. Here gathered, besides masters and scholars, the attendant scribes, followed later by the printers.

On the north bank was the 'Ville,' the predominantly commercial

* For the historical background, see vol. 11, pp. 46 et seq., of this Handbook.

Plate 10. Paris: The He de la Cite

On the island is the Palais de Justice in the foreground, with Notre-Dame Cathedral and the Hotel Dieu near the other end. There is a clear contrast between the congested streets and buildings of the 'Quartier Latin' on the left bank (on right of picture), and the more elegant tree-lined avenues and open spaces of the right bank, where the Hotel de Ville is prominent.

Plate 11. Factories at Billancourt, Paris
The great Renault works extend over a large area and have even spread to the island in the Seine.

quarter; upstream from the bridges, along the creeks and quays, grew the first 'ports' of Paris. The importance of the river traffic, which carried down to the city the wines and timber of the upper Seine basin, is seen from the growing influence of the 'Corporation of water merchants', the head of which became during the thirteenth century the chief civil officer of the municipality. The principal 'port' was on the site now occupied by the Place du Chatelet, near the Hotel-de-Ville, and close to the *croisee de Paris*, the junction of the main routes. Between the water front and the roads were established large markets, an area still partly occupied by the Halles Centrales.

The City Walls

It was around this threefold area that Philip Augustus between 1180 and 1210 built the first city wall (Fig. 27). From the eastern limit of the trading quarter on the north bank it ran in a rough semicircle, the maximum distance from the river being about 800 m., to rest in the west on the recently built fortress of the Louvre. On the south bank it enclosed the Mont Ste-Genevieve, forming the limit of the city in this direction until well into the seventeenth century. The next period of growth was therefore on the north bank, at first eastwards until the marshland along the old course of the river was reached. This marsh was gradually drained and occupied by market gardens to supply the growing city, until it was built over in the eighteenth century. The second important line of fortifications, built by Charles V about 1370, began at the Bastille and incorporated the Louvre on the west. Within the old limits the population had been growing rapidly: on a basis of a census of hearths taken in 1329 it is estimated that the population was then about a quarter of a million, a remarkable figure for the period. The new walls, however, included considerable areas of open land sufficient for some time to absorb growth which at first slackened owing to disturbed political conditions, although by the seventeenth century the city was spreading rapidly beyond the walls, mainly northwards, despite successive royal edicts establishing forbidden zones. These were partly prompted by fears of inability to feed so large a concentration, hence the preservation of the gardens of Le Marais and the attention to the water supply. The city was dependent largely upon water from the Seine, pumped directly from the river at La Samaritaine and the Pont Notre Dame. In the middle of the fourteenth century the population was nearing half a million, a stage in its development which was not materially passed until the industrial era.

The next extension of boundaries had a fiscal rather than a military reason; to facilitate the collection of the *octroi* a wall, the 'Mur des Fermiers-Generaux', was built between 1784 and 1791, with a radius some 1,500 m. larger than that of the preceding wall. This carried the northern limits of the city to the line of the old river course and

Fig. 27. The site and growth of Paris

Based on G. R. Crone, 'The site and growth of Paris', *Geographical Journal*, vol. xcvi, p. 37 (London, 1941). For the work of Philip Augustus, see vol. 11, p. 49 of this Handbook.

the foot of the northern heights. It enclosed the faubourgs which had grown up along the radiating routes and much open land, especially on the south bank. Portions of the old ramparts became the line of the great or inner boulevards.

Throughout the eighteenth century the population did not rise above half a million, but with the progress of the industrial revolution the city again pressed upon its limits. By 1841 the inhabitants

numbered 935,000, and it was then decided for military reasons to fortify a much extended area. The *enceinte* was thrown along the northern heights beyond Belleville and Montmartre and southwards towards Gentilly and Issy. This brought within the limits of Paris a number of considerable towns, for Belleville had at that time a population of 57,000 people, and Montmartre 35,000. With the incorporation in 1861 of the communes thus enclosed, the population of Paris rose to 1,690,000. The wall of the Farmers-General then became the line of the outer boulevards.

Fig. 28. The built-up area in 1839

Based on *Carte des Environs de Paris*, drawn in 1839 at the Depot Generale de la Guerre, under the direction of Lieutenant-General B. Pelet.

Industrial Growth

With industrialization and improved communications, the activities of the population also began to change markedly. Formerly, the occupation of the Parisian workers, apart from the predominating official and commercial classes, had lain mainly in trades requiring traditional skill and taste rather than an abundant supply of raw material. With the building of canals and railways, supplies of materials

for heavier industries, particularly coal and iron, became available and industry was freed from its dependence upon the river front. In the twenties there was an epoch of canal building. The Canal St Denis and the Canal St Martin were followed a few years later by the Canal de l'Ourcq. With the building of the canals the prosperity of Paris became even more closely linked to waterborne traffic, which was handled at various quays and basins along the river and the canal system, while river ports have developed up and down stream from Paris to serve the industrial suburbs, e.g. at Ivry, St Ouen, St Denis, and Gennevilliers.*

Close on the canals followed the railways. On the north bank the gaps east and west of Montmartre served as convenient routes ending at the great termini of the Gares de PEst, du Nord, and St Lazare, placed near the outer boulevards. The area enclosed in 1841 made much land available for building, and around the canal basins and stations gathered warehouses and slaughterhouses, railway goods yards and repair shops, factories and gasworks, with tenements in the neighbouring quarters to house the workers. †

While Paris was thus expanding and its industries growing, wide changes were also being made to the plan of the city. These were initiated by Napoleon III, partly on aesthetic and partly on military grounds, and the work of reconstruction was entrusted to Baron Haussmann between 1854 and 1869. Narrow streets and congested areas gave place to wide boulevards and squares (Place de l'Etoile, Boulevard St Michel); parks and gardens were laid out (Bois de Boulogne); public buildings such as the Opera were erected; and the ring of outer boulevards was built on the line of the wall of the Farmers-General. This work was naturally costly, and Haussmann met with much opposition: it is to his persistence and the emperor's support that modern Paris owes its spaciousness and its vistas.

As a result of its industrial development, the population of Paris grew rapidly after 1861, increasing by 25 % in the next twenty years. From 1881 to 1901 the rate of increase declined to about 20%, and with the beginning of this century the period of rapid expansion was approaching its close. The population reached a maximum in 1921 with a figure of 2,906,000, but this represented an increase in the preceding twenty years of 7 % only. The war of 1914-18 no doubt had

* The waterways serving Paris are more fully dealt with in vol. iv, chapter vi, of this Handbook.

† The railways serving Paris are dealt with more fully in vol. iv, chapter iv, of this Handbook.

some influence on this slowing up of the city's growth, but decline had already set in before 1911. Since 1921, the population has fallen to 2,891,000 in 1931, and to 2,830,000 in 1936, a decline of roughly 2½%. To sum up: the net result of a century of growth, 1839-1939, can be seen by comparing Figs. 28 and 29.

Fig. 29. The built-up area in 1939

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 2 (Paris, 1934), and air photographs.

Water Supply

The growth of the city has been accompanied by improvements in the water supply. Until the nineteenth century, the domestic water of Paris was drawn mainly from wells or from the Seine. The latter was raised by pumps, the first of which, La Samaritaine, was set up at the Pont Neuf in the reign of Henry IV. Later in the seventeenth century other pumps were erected at Notre Dame and at Marly for the supply of Versailles. The public fountains were, however, supplied to some extent with water from other sources, e.g. the Belleville aqueduct, said to date from the fourteenth century, and the Arcueil aqueduct, restored by Marie de Medici. These supplies were

inadequate for the expanding city, and the first step taken to obtain water from a distance was the construction in 1822 of the Canal de l'Ourcq, which for some years served as an aqueduct as well as a navigable canal. About the same time, attempts were made to utilize artesian supplies at Grenelle and elsewhere, but owing to technical difficulties these wells were abandoned. It was not until the Second Empire that the problem was solved by the engineer Belgrand, who laid the foundations of the present system. The earlier superficial supplies, were now used for public and industrial purposes, while domestic water was obtained by tapping adequate and pure supplies at the sources of distant streams; this water was led through aqueducts or underground conduits to reservoirs on the suburban heights. The first to be completed, in 1865, was that from the sources of the Dhuis, a tributary of the Marne, which carries water 114 km. to a reservoir at Menilmontant. Later, water was similarly brought from the Vanne, an affluent of the Yonne, to Montsouris (173 km.), and from the Arvre, a tributary of the Eure, to St Cloud (120 km.). More recently, Supplies for the Montsouris reservoir have been obtained from the Loing and Lunain (73 km.), and the Vanne supplies have been augmented by the Voulzie aqueduct, completed in 1925.

The water from these sources amounts to about 450,000 cu.m. per day, which is still inadequate to meet the demand, especially in summer. Some 300,000 cu.m. have therefore to be pumped from the Seine and Marne, filtered and sterilized at Saint-Maur and Ivry, and either mixed with the other water or retained in separate reservoirs. In addition, very large quantities of river water, distributed through a separate system, are used by public authorities for street cleansing, etc., and by factories, and the maximum amount that can be removed from the rivers is being approached. There have been proposals therefore to seek further supplies from the water-bearing beds in the valley of the Loire, 200 km. south of Paris, which, it has been estimated, could yield 1 million cu.m. a day. It is probable, however, that the cost of the water thus obtained would be greater than that of water from the Seine after it has been filtered and pumped up to the reservoirs. Technical improvements have now made it possible to use artesian water in the outer districts: e.g. the artesian well sunk at Aulnay-sous-Bois in 1933 to a depth of 831 m. yields 5,000 cu.m. a day for the north-western districts.

INNER PARIS

Inner Paris: Population Changes since 1841

The slowing up of the rate of increase and eventual decline in the population of Paris was accompanied by a very rapid growth in the surrounding region, but before dealing with Greater Paris something

Fig. 30

Fig. 31

Fig. 30. The decline of population in the centre of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The decline in the central districts has been most marked in those which lie to the north of the river, particularly in the arrondissement of La Bourse and in the quartier of Les Halles.

Fig. 31. The growth of population in the outer districts of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The outer arrondissements of the city have increased considerably in population; more especially those which lie to the south. These areas have a number of light industries, and they also contain the homes of large numbers of the people who work in the heart of the city, many of whom have been displaced from the centre in recent decades. Outstanding among the districts of rapid increase are Clignancourt to the north, Buttes Chaumont and Menilmontant to the east, Vaugirard and Petit Montrouge to the south, and Auteuil and Passy to the south-west.

should be said of the distribution of population within the city limits. The city, that is, the area within the *enceinte* of 1841, plus the narrow military zone around it, the Bois de Boulogne, and the Bois de Vincennes, has an area of approximately 78 sq. km. In comparison with other great cities, this is relatively small, and the average density of population (37,000 per sq. km. in 1931) is consequently high. The administrative County of London, for example, has an area almost four times as great. Towards the end of the century, in 1896, the

corresponding figure was 32,000, so that the increase in density between 1896 and 1931 was 15 %. But this increase was not uniform over the whole city.

Two tendencies have been at work. With the continually increasing scale of operations, the heavier industries which had at first tended to concentrate in the northern quarters of the city began to move outwards into the open country, where ample and cheap sites, well placed for river and rail communications, were available. As a result, the Paris region became one of the most important in France for chemical, textile, and engineering works, and in 1931, 20% of French skilled workers were resident in the departments of Seine and Seine-et-Oise. Another tendency has been the so-called ⁱ flight from the centre'. The increasing demand for sites for administrative and commercial offices, banks, large stores, etc. in the centre has led to a rise in land values, and the consequent demolition of old residential property. Moreover, the improved facilities for travel to and from the suburbs have enabled city workers to live at a distance from their work. The insanitary condition of the former densely peopled quarters has also led the municipality to demolish properties and to move the inhabitants to new quarters on the edge of the city. The result of these developments has therefore been to reduce considerably the density of the resident population in the centre of the city, to increase that of the quarters on the periphery, and to bring into existence in the Greater Paris region large industrial and dormitory towns (Figs. 31-33).

Inner Paris: Distribution of Population

Comparing the distributions of 1896 and 1931, it is apparent that Paris can be regarded as composed approximately of three zones with individual characteristics, in which varying tendencies are visible.

The centre of the city, comprising the first seven arrondissements, covers the three historic components of *cite*, *ville*, and *universite*. The most densely populated of these arrondissements is the Temple, with over 50,000 inhabitants per sq. km., followed by L'Hotel de Ville and La Bourse, all on the north bank with 25,000-50,000 per sq. km. These constitute the financial and commercial district, with subsidiary activities such as newspaper production, and have all declined in resident population. This is particularly noticeable in La Bourse, where three of the quarters decreased by more than 35 % between 1896 and 1931. It is significant, as showing the piecemeal nature of this outward movement, that the fourth quarter remains one of the most densely

populated in the city, Bonne-Nouvelle with 101,500 per sq. km., and that the St Gervais quarter of the Hotel de Ville had in 1931 the exceptionally high density of 106,900 per sq. km. The fourth of these arrondissements on the north bank is the Louvre, with a lower density of 10,000-25,000 per sq. km. This includes the central markets (Les Halles), and also an area lying between the Champs-Elysees and L'Opera, which is the centre of 'haute couture', i.e. the production of 'Paris fashions'. The reason for this localization probably lies in the former focusing of court life around the Louvre and the Tuileries. The more popular 'grands magasins' lie between this point and the commercial area. Decline in population has also been very marked here, that of the quarter of the Halles having exceeded 50%. This area is also the home of highly skilled craftsmen, working on a small scale, e.g. costumiers, tailors, gold- and silversmiths, jewellers, and leather workers, who supply the demand for luxury articles.

The portion of the central area south of the river comprises the Pantheon, Luxembourg, and Palais Bourbon. The first two, corresponding to the University and 'quartier latin', had densities of 25,000-50,000 per sq. km.; the third, containing the homes of the aristocratic families of the Faubourg St Germain, of the diplomats in the shadow of the Quai d'Orsay, and of retired officials, is less heavily populated (10,000-25,000 per sq. km.).

The second zone, on the north bank, includes the arrondissements of L'Opera, L'Enclos-St Laurent, and Popincourt. This is the area of the Gares St Lazare, du Nord, and de l'Est, of the Canal St Martin, and consequently of commercial and manufacturing activity. Thus L'Opera and Popincourt were two of the three arrondissements which still retained in 1931 densities greater than 50,000 per sq. km. The quartier Rochechouart of L'Opera had the high density of 90,300 per sq. km., and was the sole area in this zone which increased during this period. The decline elsewhere was largely due to the spread of business houses and luxury shops in this direction from the centre: as a result, one district adjacent to La Bourse, the 'quartier de la Chaussee d'Antin', had decreased by more than 50%. The decline was less marked in Popincourt, which is largely a district of workers' tenements, with a large foreign element.

The third zone is that of the outer ring of arrondissements, mainly industrial and working-class areas, e.g. Batignolles, Montmartre, Chaumont, and Vaugirard, with a density in general between 25,000 and 50,000 per sq. km. This ring is broken at one point in the south-west by wealthier residential districts on the heights of Passy. Save

in a few minor districts, the population of this zone increased markedly since 1896. High increases of over 150% occurred in the manufacturing area of Vaugirard, and in Passy; several other quartiers increased by 65-120%. Though not the scene of heavy industries

Fig. 32. The density of population in the department of the Seine, 1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 20 (Paris, 1934).

In the city itself the greatest densities are found to the north of the Seine. In the remainder of the department the principal area of high density lies to the north-west on both sides of the Seine—at Neuilly, Clichy, Puteaux, Courbevoie and Colombes. This distribution largely reflects the distribution of industry in Greater Paris. B, Bois de Boulogne; V, Bois de Vincennes.

similar to those of Greater Paris, these exterior arrondissements have a variety of industries, such as the furniture factories of the Faubourg St Antoine (Batignolles), the boot factories of Belleville, and the light metal works of Charonne, apart from those more directly associated with the railways. These areas are also the homes of those displaced from the centre who work daily in the city and the west.

GREATER PARIS

Growth of Population

The boundaries which should be assigned to Greater Paris are not easy to determine precisely. During discussions in 1932 on future

Fig. 33. The growth of population in outer Paris, i.e. the department of the Seine outside the city limits, 1876-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 22 (Paris, 1934).

While the increase has been fairly general, it has been most marked to the north and north-east, and in some areas to the south. It will be noted that these areas lie mostly away from the city limits, for by 1876 the communes immediately adjoining Paris had already begun to experience a growth of population spreading outward from the city. These more remote communes, such as Gennevilliers and Colombes to the north-west, La Corneuve, Le Bourget, Drancy, Aubervilliers, Pantin, Bobigny and Villemomble to the north-east, and Gentilly, Villejuif and Sceaux to the south, had very small populations in 1876, and with the spread of industry in recent decades their growth has appeared all the more striking.

growth it was declared to consist of the department of the Seine, those communes of Seine-et-Oise and Seine-et-Marne within a radius of 35 km. of Paris, and a large proportion of L'Oise, forming an area

Fig. 34

of approximately 5,000 sq. km. with a population of 6,300,000. This deliberately included areas not then dominated by Paris: but whatever the exact boundaries, there is no doubt that the whole of the department of the Seine falls within Greater Paris, and recent censuses show how rapid has been the growth of its population. In 1881 the department, excluding Paris, had 530,000 inhabitants: this figure, by 1901, had nearly doubled (956,000), and trebled by 1921 (1,506,000); by 1936 it was 2,133,000, comparable with that of the city itself, with an average density of approximately 5,300 per sq. km. (Figs. 32, 33).

Development in these outer regions has spread along the lines of communications, absorbing long-established towns, and generally repeating the characteristics of the city's quarters thus extended—industrial areas on the lower, more accessible land, and residential suburbs on the higher. Four industrial areas are conspicuous : * (1) the north and north-eastern, comprising St Denis, St Ouen, Aubervilliers, and Pantin; (2) the west and north-western, spread along the winding valley of the lower Seine (Fig. 34); (3) the south-eastern, in the upper Seine valley as far as Choisy and extending west to the valley of the Bievre; and (4) the south and south-western, adjoining the city limits in the Gentilly, Vanves, and Arcueil areas, and extending westwards to Issy-les-Moulineaux.

North and North-eastern Industrial Suburbs. The first of these is of considerable importance. The basis of its development has been the St Denis canal, which, via the Canal de TOurcq, brings Pantin on the east within the area. The important industries of St Denis produce locomotives and wagons, engineering and electrical equipment, acids, fertilizers, soaps, etc., and along the Seine ships and barges are built. St Ouen to the south has a number of very diversified industries, generally of a lighter character—copper and aluminium

* For details of industry, see pp. 177-9.

Fig. 34. The industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The line of the 1841-5 fortifications is represented by the circular line of railway, except to the east where it is marked by a belt devoid of factories. Thus to the north, north-west and south-west most of the factories lie outside the city limits, while to the east and south they lie more within them. It is clear that the location of the larger factories is much more closely related to the river and to the railways than to the canals. The Port de Gennevilliers is a barge port of recent construction, in which the two existing docks will be followed by others, the whole system being designed to serve the growing industries of Colombes, Gennevilliers and Argenteuil.

goods, tinned foods, furniture and pianos, gloves from skins. The industries of Aubervilliers, La Courneuve, and Pantin are predominantly chemical, ranging from oil refining to perfumes and toilet articles, while the by-products of the Villette slaughterhouses are used for the manufacture of tallow, margarine and leather. In these districts the available labour has attracted many minor factories,

Fig. 35. The metal industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

These include mechanical and constructional engineering and a variety of metal manufactures. The majority of these factories lie to the east and south.

producing, for example, glass and pottery at St Denis, and sewing cotton and tobacco at Pantin. These five communes form a block of over 240,000 inhabitants, which increased between 1921 and 1936 by approximately 15%, despite a marked decline in the depression following 1931. This manufacturing area is spreading north-eastwards towards the rail and air centre of Le Bourget, competing for the available land with the builders of housing estates, who have been particularly active around Drancy (Figs. 28, 35).

West and North-western Industrial Suburbs. The second great industrial group is in the west and north-west, established along the valley of the Seine. Immediately west of Paris is the centre of the French motor and aircraft industries, with the Citroen works at Grenelle and the Renault at Boulogne-Billancourt (Plate II). Here

Fig. 36. The electrical, automobile and aircraft industries of Greater Paris, 1939. Based on (1) *Carte Industrielle de la Région Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The concentration of these industries to the north-west and south-west is clear. Figs. 35 and 36 are complementary, and show between them all the metal-using industries. Fig. 35 shows mainly old-established industries; Fig. 36 shows newer industries.

expansion has been rapid, the population of the latter commune having increased from 68,000 in 1921 to 97,000 in 1936. Farther downstream, on both sides of the valley, extends a string of industrial concentrations combining the engineering and manufacturing activities of their neighbours to the north and south: Suresnes, Puteaux (armaments), Courbevoie, Levallois-Perret (motors and aircraft), Clichy (gas works and oil refineries along the river), and Asnteres (chemicals

and foodstuffs). The population of this zone exceeds 380,000, having increased by approximately 20 % between 1921 and 1936. Expansion has progressed in the loop of the Seine towards Argenteuil, notably around Gennevilliers, where there is a large electric power station fed by water- and rail-borne coal. Interlaced with these and standing on the higher ground are residential suburbs, e.g. Neuilly, Nanterre and Colombes (Fig. 36).

South-eastern Industrial Suburbs. The industrial areas are repeated on a somewhat smaller scale in the south-east along the Seine valley through Ivry and Vitry, where there are large power stations and gasworks. Vitry, however, still continues to grow flowers for the city markets, whilst Choisy manufactures linoleum, paper and china. Here live a population of some 120,000.

South and South-western Industrial Suburbs. Another industrial belt extends to the west, skirting the city limits as far as the Seine; its features are the tanneries and laundries in the valley of the Bievre around Gentilly which perpetuate the early use made of its waters, and Issy-les-Moulineaux, with its power stations, munition and cement works, breweries, and tobacco factories. This sector has a population of over 200,000. From its western end a series of small towns continue southwards over the broken plateau, and house thousands who work daily in Paris; these towns, interspersed with market gardens, carry the boundaries of Greater Paris beyond Sceaux. The recent electrification of the railway line serving this area may be expected to stimulate the further development of dormitory estates.*

Eastern Residential Suburbs. In this circuit of Paris one sector has so far been omitted, the eastern, which has become the predominantly residential area of the outskirts, beyond the factories along the eastern border of the city. Extending over the gentle and formerly wooded hills north of the Marne as far as the boundary of the department are numerous residential towns such as Vincennes, Montreuil, and Fontenay-sous-Bois, with islands of orchards, vegetable and flower gardens, scarcely touched by industrial development. Nearly a quarter of a million people have their homes in this sector of Greater Paris. Similar expansion has taken place along the valley of the Marne, the tide of building progressing from one loop of the river to the next as far as Nogent. The peninsula between the Seine and the Marne is occupied by the working-class suburb around Alfortville comprising some 75,000 inhabitants. In the first great loop of the Marne is the garden city of St Maur (57,000); in the next Champigny (27,500),

* See vol. iv, chapter iv, of this Handbook.

and again in the next Nogent and Le Perreux (together 45,000), developments all consequent on the breaking up of large estates towards the end of the last century. Market gardening is still carried on to some extent, but except around Alfortville and Maisons-Alfort there has so far been little industrial development.

Regional Planning

This development of the Paris region has been haphazard and unco-ordinated. Factories and housing estates are intermingled: the new quarters of the expanding towns are often unprovided with adequate roads, drainage, or water supply: valuable agricultural land has been built over: and natural amenities have been destroyed. This has resulted from the lack of a central authority, the constituent communes being largely independent and without the means to develop in an orderly way. In 1932 a law prescribing a 'projet d'aménagement' for the whole region was promulgated. A general directing plan was drawn up and presented in 1934, with which the local schemes were to conform. It covered the lay-out of the main roads, open spaces, the use of the land and the regulation of buildings, public services, and the protection of sites. The scheme for communications provided for five radial motor roads in conjunction with an outer ring at a distance of some 20 km. from the centre.* For several reasons, among which the conflict of local interests is not the least important, progress with the scheme has been slow.

Attempts have also been made from time to time to check the continued concentration of industries, particularly aircraft works, in the Paris region, as this was considered to be strategically dangerous. In 1931 a fund was instituted to assist the removal, if required by the Air Ministry, of aircraft factories to a particular zone, and the scope of this measure was afterwards enlarged. Three years later the Departments of National Defence ruled that works thereafter established in the region should in general be excluded from their supply lists, and in 1938 official approval was required for the siting of new munition factories. It does not appear that this movement had made any considerable progress before the outbreak of war, one obstacle being the disinclination of the workers to migrate with the factories.

BIBLIOGRAPHICAL NOTE

(1) An account of the geographical factors important in the development of Paris will be found in the following articles and books:

See vol. 1, p. 249, of this Handbook. A detailed map showing the density of population in Paris and the Paris region in 1931 can be found in the *Atlas de France*, Plate 72 (Paris, n.d.).

Chapter III

AGRICULTURE

Introduction: Wheat: Other Cereals: Root Crops: Minor Crops: Wine and other Beverages: Market Gardening: Livestock: Working Population: Land Tenure: Legislation: Forests: The Vichy Regime: Bibliographical Note

INTRODUCTION

France is a country highly favoured by nature from the point of view of agricultural production. Of its working population, 35% are engaged in agriculture, and the urban areas are to a great extent fed by home-grown food. A map showing density of population exhibits a remarkable continuity in distribution; only in the highest parts of the Alps and the Cevennes and on the sandy forested stretches of the Landes are there any considerable empty areas. Cultivation penetrates far into the highlands of the Alps, the Vosges and the Jura, following the terraces of the river valleys; it covers the lower platforms of the Central Massif; it renders return, however meagre, even to the dense population of the poor acid soils of Armor in Brittany. If pastoral pursuits and forestry are included, there is hardly a corner of the country left unproductive.

Climate, soil and relief have greatly contributed to this high degree of land utilization, and to these factors must be added the late development of French industry. Both climatic and soil conditions present considerable variety. Exposure to Atlantic winds precludes the harsh winter conditions of more northerly and more continental areas, so that the sheltered bays of the Breton coasts are able to grow early vegetables for export. The extension southwards to Mediterranean shores and the protection afforded by the Cevennes and the Alps against northerly winds give to France a share in Mediterranean products, and have made possible the large-scale cultivation of *pruneurs*; yet, except in the Rhone delta and the eastern-facing valleys of the Pyrenees, the summer drought is not sufficiently prolonged to make cultivation entirely dependent upon irrigation. In the east of the country there is an approximation to continental conditions of agriculture, with the cultivation of maize, hops and tobacco in the lowlands. Finally, the ample development of mountain and plateau in the south and south-east with Atlantic-facing slopes is the basis for pastoral and forest industries.

A generalized view of the soils of France is difficult, partly because of the variety of soil types within a small area, partly because centuries of intensive cultivation, marked even by the transference of soil from one locality to another in barges, has made the present distribution in some areas almost artificial. Despite this, certain predominant soil groups are apparent. The most important contrast is between mountain and lowland soils. The former vary from the rich soils of the volcanic districts of the Central Massif through the moderately fertile calcareous soils of the Jura to complete poverty in parts of the Alps and Pyrenees. Acid soils, too inaccessible for economic liming, must be content to produce such 'poor man's crops' as rye and buckwheat. The lowland soils are equally variable—from the poor sands of the Landes and the sands underlain by clay of the Sologne to the rich alluvial deposits in the river valleys. The prevalence of limestone and chalk ensures large areas of warm, well-drained land; the distribution of *Union* on these high, limestone plains of northern France provides a fairly heavy, loamy soil, suitable for wheat, sugar beet and other root crops. Sunny, south-facing slopes on well-drained limy or gravelly soils produce vines as far north as the river Aisne (Fig. 46). Alluvial river terraces, especially when covered with loessic deposits, are intensively cultivated throughout the land. Ill-drained valley bottoms, moorland, coastal marshes and mountain shoulders or 'alps' provide meadow and permanent pasture.

Upon these diverse soils the intensive cultivation of the small farmer has in many places developed a specialized agriculture, but taking the country as a whole, the yield per hectare is a moderate one for western Europe. It is considerably lower than the yield in such countries of intensive peasant farming as Holland, Belgium and Denmark, and also appreciably lower than the yield in the United Kingdom and Germany, as shown in the following table:

	Yield (quintals per hectare) 1933-7 average			No. of livestock per 100 ha. of cultivated land, permanent meadow and pasture, 1937	
	Wheat	Barley	Oats	Cattle	Pigs
France	15'3	14'3	14'0	45	20
United Kingdom	22'8	20'6	20'4	48	36
Germany	22'2	20'9	19'9	71	83
Belgium	26'5	26'1	26'5	88	52
Holland	29'6	28'7	23'9	109	71
Denmark	31'3	28'4	25'9	93	111

From *Annuaire Statistique*, 1938 (Paris, 1939), which gives *Tableaux Retrospectifs* for a number of countries.

A comparison of the densities of "livestock likewise reflects the different agrarian economies of these countries. Figs. 37 and 38 show the percentages of arable land and grassland respectively in each department in 1938. The proportion of the total agricultural land devoted to each type of farming activity is shown in Fig. 39. The adjoining table summarizes the agricultural production of France.

Summary of Agricultural Statistics, 1938

	Hectares	Quintals (except where otherwise stated)
Cereals:		
Wheat	5,050,199	98,010,002
Oats	3,245,257	54,574,380
Barley	759,223	12,907,804
Buckwheat	261,366	2,422,894
Rye	631,096	8,111,314
Maize	340,290	5,786,067
Millet	9,212	88,266
Other products:		
Potatoes: New	113,235	9,266,727
Others	1,425,000	173,145,000
Sugar beet	319,000	79,800,000
Fodder beet	976,000	382,600,000
Flax	38,000	238,000
Tobacco	18,100	33,166,280 kg.
Hemp	3,802	41,873
Grapes	1,567,000	60,300,000 hl.
Hops	1,600	21,3'00
Cider	—	34,600,000 hl.
Market gardening	437,000	—
Olives	—	333,000
Livestock:	Numbers	
Cattle	15,622,000	
Sheep	9,872,000	
Pigs	7,126,000	
Horses	2,692,000	
Milk	133,241,000 hi.

WHEAT

In few parts of France are to be found the cool damp conditions that preclude the successful growing of wheat, as in western Britain, and as a result the area under wheat is half that under all cereals. The age-long localization of grain varieties enables most soils that are cultivated with intensive assiduity to be used.

The more important wheatlands (those with an average departmental production of over 2½ million quintals per annum) are situated in the departments to the north and east of Paris (Fig. 40). These areas

Plates 12, 13. Farms in the Bourbonnais

The Bourbonnais lies on the northern edge of the Central Massif between the rivers Cher and Allier. Plate 12 (above) shows the large establishment typical of a former social system; the fifteenth-century *Maison du Maître* lies adjacent to the dwellings of the *metayers* on the left. It is more common for the former to have a separate existence as a chateau. Plate 13 (below) is of a small farm more typical of modern French agriculture.

mainly comprise low limestone plateaux providing a well-drained subsoil covered with fertile surface loams. Wheat is also cultivated intensively on the alluvial terraces of the Seine and its tributaries (Plate 15). Districts with over 15.5 quintals per hectare stretch from the Seine valley to the Belgian frontier. Other areas of high yield are Languedoc, especially on the lava soils, the basins of the middle Rhone, the lower

Fig. 39. Utilization of agricultural land, 1938

Charente region in northern Aquitaine, and the upper valleys of the Mayenne and the Sarthe. Next come the coastal plains of western Brittany, Normandy, the Alsatian terrace lands, and the terraces of the lower valleys of the Alps and Pyrenees. The mountainous regions, together with the coastal regions of the Landes and the Mediterranean, are least important, although even there small areas of relatively level land are utilized (Plate 19).

The area under wheat decreased towards the end of last century as less favourable lands went out of cultivation. Between 1914 and 1918 the decline was rapid due to the ravaging of the north-east by war. Since 1919, the gradual recovery of these areas has been balanced by

Fig. 40. Production of wheat in quintals per 100 ha. of each department, 1938

a steady decline in the south and in other districts such as Normandy, where wheat occupied in 1933 only two-thirds as much land as in 1913. The latter decrease was due in part to the competition of dairy farming. As a result, the total area under wheat has remained relatively constant since 1923 but with a slight tendency towards decline. There has been some restriction in wheat growing as part of a general policy

of avoiding over-production. In 1933, producers were put on an area quota based upon an average of the three preceding years. The yield per hectare, although obviously masked by good or bad harvests, has

Fig. 41. Production of cereals, 1924-38

risen steadily, partly because less favourable lands have gone out of cultivation and partly because of an increased use of fertilizers (chiefly of superphosphates, potash, basic slag, etc.). Thus, although the area under wheat has declined by about 20 % since 1913, the increased yield has resulted in six harvests (those of 1925, 1929, 1932, 1933, 1934 and

Plate 15. Arable farming in Beauce

A photograph taken east of Chateaudun, showing the broad, flat, almost treeless expanse of intensively cultivated land.

Plate 16. Sheep-folding in Beauce

As in Britain, sheep folded on stubble or roots are an essential part of the arable farming economy of limestone regions such as this.

Plate 17. The Champagne Plain

View eastwards from Mt Aime, about 30 km. west of Chalons-sur-Marne. The level or gently undulating plain is between 100 and 150 m. above sea level. Hedgeless cultivated fields alternate with strips and rectangular blocks of planted pines.

Plate 18. Grain elevator near Castelnaudary (Aquitaine)

France is largely self-supporting in grain, and in consequence large quantities are stored at inland towns and not necessarily at the ports, as in Britain. The majority of elevators are owned by co-operative societies, in this case by the *Greniers reunis des agriculteurs Lauraguais*.

Maize yielded 5¾ million quintals in 1938, and it is important only in the south-west where conditions are moist, warm and virtually frost free. It is grown mainly as a fodder crop, and large supplementary quantities have to be imported. Small quantities are cultivated throughout eastern France—a reflexion of the increasing incidence of summer rainfall.

Millet. Only 88,000 quintals were produced in 1938, and of this Vaucluse, a department consisting largely of the Fore-Alpine limestone plateaux, grew almost one-half (41,000 quintals).

ROOT CROPS

Potatoes. Nearly 3 million hectares of ground are under roots and kindred crops, and almost half of that total (i.e. 44%) is occupied by potatoes. They are grown very widely for local consumption, and as the total crop exceeds the requirements for human consumption much of it is fed to pigs or used in the manufacture of alcohol and starch. Two districts specialize in the crop, namely, Brittany, which produces new potatoes, and the area around Strasbourg. Up to 1932, France exported a large amount of early potatoes, especially to Great Britain, but the extension of the Colorado beetle into Brittany has considerably reduced this trade.

Beet. Both fodder beet and sugar beet are grown to a considerable extent in France, roughly in the proportion of four to one respectively. Fodder beet is grown widely in the northern plains, chiefly for the fattening of stall-fed animals. Sugar beet is localized in the extreme north and around Paris (Fig. 43). The beet is grown on large farms in conjunction with wheat, both crops benefiting by the rotation.

Although many sugar refineries were destroyed during the war of 1914-18, the general rise in the standard of living since then has almost doubled the consumption per capita of sugar; the number of refineries is still below the 1914 total, but their output is much greater. The total number of refineries in France is 111, and of these seventy are situated in northern departments. The changes in this area are summarized below:

Refineries in Operation

	1912-13	1920-23	1928	1938
Nord	40	13	13	13
Pas de Calais	24	8	12	12
Somme	33	7	9	14
Oise	20	16	18	18
Aisne	51	11	13	13
Total for five northern departments	168	55	65	70

Fig. 44. Production of wine in hectolitres per 100 ha. of each department, 1938

At the same time as home production increased, sugar imports from the colonies increased almost fourfold compared with pre-1914 totals. As sugar stocks accumulated and the price of beet fell, an agreement was negotiated in 1931 between growers and refineries whereby the price of beet was fixed relatively to the price of sugar, and the refineries accepted voluntary quotas. At the same time the French colonies undertook to limit their shipments to 13 % of the home-produced total. Thus the industry achieved a certain equilibrium without state control, and the area under cultivation has fluctuated but little.

In addition to the utilization of the beet crop for sugar-refining, large quantities are sent to distilleries for the manufacture of alcohol.

MINOR CROPS (Fig. 45)

Flax is grown in the north-eastern departments in the Scarpe and Lys valleys, where a multitude of watercourses makes flax-retting easy. It does not, however, occupy more than 1½ % of the total arable land of the two most important producing departments of Seine-Inferieure and Nord. After a revival which reached a maximum in 1929 (79 % higher than in 1913), economic depression hit the industry, and in 1931 21,000 ha., almost two-thirds, went out of cultivation. The crop has been revived in recent years by a substantial state subsidy and has shown a striking increase since the lowest yield in 1932. In 1938, it was again above the 1913 total.

Tobacco is grown under state regulations and with a subsidy to a small but increasing extent in the south-west (Plate 20), in the two Rhine departments, and to a much less extent in the north-eastern departments and in those of Savoie, Isere and Drome. In Alsace it forms one of the two main crops of the reclaimed Rhine flood-plain—hops being the other.

Hemp is grown to a very small extent by state subsidy in the Loire valley, but in no department does it exceed more than 0.5 % of the arable land

WINE AND OTHER BEVERAGES

Production. France is the most important wine-producing country in the world, although Italy has a greater area under vineyards. But the French yield per hectare (401.) is almost twice that of Italy (22'11. per ha.), and in the production of fine wines France stands alone.

The vine, while not unduly exacting, as it is able to withstand periods of frost, requires a moderate rainfall in spring and early summer with strong continuous sunshine during the late summer and autumn. It grows very widely (Figs. 44, 46) on most types of soil, preferring well-drained stony or gravel soils. The effective northern limit of

Fig. 45. Production of flax, hemp and tobacco, 1924-38

the vine is shown on Fig. 46. The bleak uplands of the Central Massif are obviously not suitable, while the southern Landes and western Pyrenees are subject to warm moist air which encourages mildew. It is interesting to note that the marginal areas of the north, where exceptional and intensive care is necessary, produce some of the best vintages.

Plate 19. Grain harvest in upper Dauphine

Almost every patch of level land in the mountains, snow-covered in winter, is utilized in summer to produce crops of hay, grain or potatoes.

Plate 20. Tobacco cultivation near Beynac (Dordogne)

The rolling limestone country of eastern Aquitaine yields good soils on well-drained slopes. Most of the small farms have a field of tobacco (a carefully cultivated and remunerative crop) and a number of fruit trees.

Plate 21. A Champagne cave at Reims

Storage at even temperature in caves hollowed out of the chalk assists the maturing of the

Vine growing is mainly in the hands of small-scale cultivators, as a vineyard in full bearing fetches a high price per hectare. In 1924, 82 % of the 11 million growers who declared their output had holdings smaller than 2 ha. The remaining large holdings are found chiefly in the Garonne-Dordogne area, where famous Chateau vintages are

Fig. 46. Main wine-producing centres

Based on *Guide Michelin*, p. 28 (Clermont-Ferrand, 1939).

produced, a few in the Loire valley, and a very small number in the Champagne district. Many of the vintage wines such as those of Burgundy are grown by small cultivators and blended by large merchant firms.

Normally over half of the French output comes from the Midi. The grape grown is largely the *petits vins* cultivated on an extensive scale, and it provides the cheap *vin ordinaire* so widely consumed within

the country. The centres of the Midi wine industry are at Beziers, Nîmes, Perpignan and Montpellier (Plate 21).

The second great wine-producing area is in the south-west, and follows closely the valleys of the rivers Garonne, Dordogne and Charente, with Bordeaux as headquarters. About a quarter of the French total comes from here. Four distinct localities produce the high-grade vintage wines. The Medoc region yields fine clarets; south of Bordeaux is the Graves area; on the hills north of the Dordogne lies St Emilion; finally, the much smaller Sauternes district lies on both sides of the Ciron, a tributary of the Garonne. In south-western France are the brandy-distilling areas of Cognac, including the greater part of the departments of Charente and Charente-Inferieure, and the less important Armagnac district in the department of Gers, south of the Garonne.

Another group of wines are the Burgundies, which come from lower Burgundy (the Chablis district), the Maconnais and the Beaujolais; the most important area is the Cote d'Or, between Dijon and Chagny. Here the soil and climate are exceptionally favourable, and owing to scattered villages and the large number of small growers the wines differ widely. About one-twelfth of the French total is produced in this district (Plate 23).

The Champagne area lies in the department of Marne. The four main districts are (1) the slopes of the limestone hills known as the Montagne de Reims; (2) the Cote des Blancs south of the river; (3) the Marne valley itself; (4) and, finally, the lower slopes of the chalk escarpment in the extreme east of the department. The wine, which is essentially an artificial product blended from the output of all of these districts, is the result of careful culture, pressing, fermenting, maturing and blending. The production, however, is inconstant and constitutes a very small proportion of the French total, averaging only about a quarter of a million hectolitres (Plate 21), although in a 'good vintage' year the value is considerable.

Another important wine-producing district is in the Loire valley. The chief areas are in Anjou and Touraine, which yield such famous wines as Vouvray and Saumur; the coastal departments produce white wines such as Muscadet, and the rest of the valley produces large quantities of *vin ordinaire*. The production averages about 5 million hl., about one-twelfth of the French total.

Alsace-Lorraine is also a small producer of wine. The vines are grown on the lower slopes of the Vosges and in the eastern valleys, sheltered from winds and with sufficient sunshine (Plate 24). Much

of the wine is of ordinary quality, but such white wines as Muscatel, Riesling and Turckheim are exported.

Finally, in the Jura a number of notable wines, such as Ch&teau-Chalon and Arbois, together with much *vin ordinaire*, are produced.

Output. The area under vines grew steadily to a maximum of 2,447,000 ha. in 1874; the production of wine for market reached a total of 83.8 million hl. in the following year, a figure which has never again been reached (Fig. 47). Only about 3 % of this total was exported, but in value it was a much greater proportion of the whole. By 1879, production had sunk to 25.8 million hl.; this startling decline was due to the ravages of the *Phylloxera*, an insect native to the United States which had been introduced into Europe between 1858 and 1863 with American vine stocks. The insect multiplied at an enormous rate and attacked the roots of the highly susceptible European stocks, thus tapping the flow of sap and destroying the

Fig. 47. Production of wine and cider, 1830-1938

vine. Over a million hectares of vineyards were destroyed in France, and the financial loss is estimated to have been much greater than the indemnity paid to Germany after the Franco-Prussian War. The pest was overcome by (1) the large-scale introduction of a relatively immune American stock upon which the French vine was grafted, (2) the injection of carbon bisulphide into the ground, and (3) winter flooding where practicable. But the quality of subsequent vintages suffered, and in many localities vine growing was permanently abandoned. By 1911, an area of some 1½ million ha. was under the vine, producing about 45 million hl., and this area has remained relatively stable.

But although the *Phylloxera* was conquered, the wine industry never went back to its previous prosperity. During the years of low production, Spanish, Italian and North African wines made considerable headway. Algeria, being within the French customs territory, rapidly increased its output and sale in France. In addition, the cultivation of the vine in other parts of the world, notably in

South Africa, Australia and South America, caused further decline in French wine exports. South American wines hit especially the export of *vin ordinaire* from Bordeaux to the Latin republics.

The diversion of labour from agriculture during 1914-18 left* the vineyards open to disease, and in 1915 two-thirds of the crop was lost owing to mildew. Since that time the industry has recovered somewhat, but it has been hit by the heavy and increasing English excise duties, by Prohibition in the U.S. between 1920 and 1933, after that by the relatively small import quota allowed by the U.S., and by the general world economic crisis, wherein wine as a luxury product suffered severely.

As wine is the principal drink of the country, it is likely that the total amount produced is very many times that exported. But the home consumption has fallen greatly, owing to the general economic crisis, to unduly high prices, and to the greater adoption of other beverages such as beer and cider. Between 1931 and 1933, many of the great proprietors became bankrupt and their estates were broken up for sale. Since 1933, however, there has been some degree of recovery.

Beer and *cider* are the principal beverages in the areas where the vine cannot be successfully grown, although the first is increasing as a drink generally. *Beer* is produced chiefly in the north and east, *cider* in the north-west. Hops are grown in Alsace and Burgundy, but from the latter area they are sent to the breweries in the Nord and Rhine departments. Both the area under cultivation and the total yield fluctuate considerably. *Cider* is the normal beverage of Brittany and Normandy, and is produced in the apple-growing departments that border the English Channel. The chief feature about the yield is its variability (Fig. 47). Thus the yield in 1938 (34.6 million hi.) was more than twice that of 1937.

MARKET GARDENING

In many parts of France climate and soil, together with intensive skilled labour, have resulted in the localization of special crops. Adjacent markets in large towns have encouraged the large-scale production of 'perishable' commodities which command a good price. With the organized development of fast main-line trains with refrigerator cars (notably by the P.L.M.) and of motor transport, district surpluses have been sent farther afield. Thus Vaucluse and Var are able to send fresh produce to Paris, while a large amount of table fruit,

Plate 22. A vineyard near Narbonne (Aude)

Extensive vineyards in the Midi yield vast quantities of *petits vins*, grown and processed for the production of cheap *vin ordinaire*.

Plate 23. A Burgundy vineyard

The typical unit of production in the wine industry of Burgundy is the *dos*, of relative y small extent, from which the vintage derives its name—in this case Clos-Vougeot. Behind the chateau is the escarpment of the Cote d'Or.

Plate 24. Vineyards at Ribeauville (Alsace)
Alsatian vines are grown on the lower south-facing slopes of the Vosges.

cut flowers and other luxury produce from Provence appears in the London markets. As a result, in 1938, 143,042 people were engaged exclusively in the cultivation of fruit and 39,084 people in the cultivation of flowers. Of the total area devoted to horticulture in 1938 (that is, about 437,000 ha.) 304,000 ha. were cultivated for subsistence and the remainder for the production of cash crops for market—vegetables, fruit, flowers and shrubs (Plate 25).

Vegetables. In mild damp regions, such as the sheltered bays of Brittany and the Marais Poitevin, early products (*primeurs*), notably cauliflowers, new potatoes, onions and tomatoes, are cultivated for markets in Paris, England and the industrial north-east of France. The lower Rhone valley offers similar possibilities over a longer period of the year, and in Provence and Roussillon all types of early vegetables for salads are grown. In many districts, vineyards have been uprooted to make room for the more lucrative production of *primeurs*. Here irrigation, protection from the mistral by cypress and wattle fences, and smoke screens against frost are necessary (Plate 26). Around the large towns, market gardening and glass cultivation produce vegetables for the urban markets. In certain districts, notably round Bordeaux and Metz, peas, beans, asparagus, etc. are grown for canning and bottling.

Fruit. In a climate which has much sunshine fruit growing will clearly be important. The commercial production of fruit is carried on in many areas, and once again localized specialization is the case. Notable features are fruits for canning and crystallizing in Gascony, high-class dessert fruit of all kinds in the Rhone valley, cherries for bottling and sugaring in the upper Rhone area, black currants for making *cassis* round Dijon, almonds, figs and citrus fruits on the Mediterranean coast, walnuts in Isere, chestnuts on the Central Massif and the olive on the south-facing terraces of the Midi. The last is near the northern climatic limit and frosts may be destructive, but some oil is produced for margarine and soap as well as for export in a refined state. As in most Mediterranean lands, much olive oil is used locally for a wide variety of domestic purposes in place of animal fats.

Flowers are cultivated on the Cote d'Azur for making perfume and for the 'cut-flower' export trade; the centre is Grasse (Plate 27). Another example of large-scale specialization is the production of roses in Brie and Provins.

Silk. The cultivation of the mulberry may be linked with market gardening. It is cultivated on the lower slopes of the middle Rhone valley and of the Mediterranean coast, but the production of home raw

silk has decreased greatly. The cottage industry of silkworm rearing was halved between 1913 and 1936, largely due to competition by imported raw silk from Piedmont, Syria and the Far East. Production of silk is carried on in seventeen departments, the most important being Gard, Drome, Ardeche, Var and Lozere (see pp. 239-40).

LIVESTOCK

There are three types of natural pasture in France, namely, the upland type, the lowland *bocage* type, and the smaller areas of coastal saltmarsh.

The summer upland pasture is very varied. It includes the *alpages* or *alps* between the permanent snow-line and the tree-line (Plate 28). Animals are taken there from the valleys in early summer to graze until autumn. Other varieties of upland pasture include on the one hand the scanty herbage of the limestone Causses and the heath pastures of crystalline uplands, and on the other the better pasture of the well-watered lower plateaux such as Limousin, and of the rich volcanic soils of parts of the Central Massif.

The lowland *bocage* type is found where the rainfall is evenly distributed throughout the year and where conditions are mild, as for example in Normandy, Brittany and Vendue. The rank grass is suitable for cattle grazing. In general, too, hay meadows are conspicuous features in the broad clay vales that separate the higher limestone plains in northern France.

The third type is saltmarsh pasture found notably in the Crau and Camargue districts of the Rhone delta, and along the Vendee and Breton coasts.

The distribution of permanent pasture is shown on Fig. 38. The rearing of stock is, of course, not confined to these natural pastures, but is carried on in many places in conjunction with arable farming (Plate 16).

The number of cattle has risen slowly from 1875 to 1938, with but little break during 1914-18, and has stabilized at about 15 ½ millions. Sheep, however, decreased sharply during that period to just under 10 millions and are still significantly below 1913 figures; and pigs also declined, although they recovered their pre-1914 numbers in the next twenty years. The large war-time losses of horses had been almost made good by 1929.

Cattle are reared in most parts of France (Fig. 48), the least important area being along the Mediterranean coast, although even

Fig. 48. Distribution of cattle per 100 ha. of each department, 1938

Fig. 49. Distribution of sheep per 100 ha. of each department, 1938

there the Camargue is rather an exception. One important cattle area is the Armorican peninsula, despite the high proportion of ploughland and the low proportion of natural pasture. The Cotentin department of Manche has a greater density of cattle than any other in France; its cattle average 91 per sq. km. compared with the general French average of 29; the corresponding figures for milch cows are 51 and 17 respectively.

On the Central Massif, cattle are reared in the departments of Cantal and Haute-Loire, and in the more northerly departments of Allier and Saone-et-Loire (the natural pastures of Charolais (Plate 32)). An outstanding breed is the Salers. The animals are grazed in summer on the pasture of the volcanic soils of the plateau and are hay fed in the valleys in winter. Other important districts are in Picardy and Artois, in the Vosges, in Savoy, where the Tarentaise breed are kept, and in the Pyrenean foot-hills. Transhumance, that is the seasonal movement of animals to the high pastures in summer, is practised in nearly all upland areas.

Dairying is most important in Normandy, the Charente, Jura and Savoy. On the whole, production is backward and milk yield low, due to the multiplicity of breeds which hinder the organization of breeding societies, to the lack of a farming aristocracy interested in scientific breeding, to insufficient supplementary feeding of roots and oil-cake, to the prevalence of disease such as tuberculosis, to bad housing, and to lack of co-operation. Only in the Charente, and to a less extent in Normandy, Savoy and Jura, is there much co-operative organization. Although far below Danish or Dutch standards, Charente butter fetches the highest price on the Paris market.

Co-operation in the Charente

	No. of societies	No. of members	No. of cows	Milk handled, million litres	Butter produced, tons
1883	1	90	330	0'6	31
1908	112	67,026	165,021	246	11,636
1928	134	87,694	263,303	446	19,647
1938	134	77,820	271,539	447	19,775

From P. L. Yates, *Food Production in Western Europe*, p. 267 (London, 1940).

Other parts of France have a number of small-scale co-operative dairies but primitive independence is more usual. By far the greater **part of** butter and cheese is made on the farms or in the dairy chalets in the mountains. Such varieties as Gruyere in Savoy and Jura,

Plate 25. Market gardening at Chatillon (near Paris)

In the Paris suburbs, as around many great cities, vegetables are intensively cultivated.

Plate 26. Cultivation of *primeurs* at Chateau-Reynard (near Avignon)

Early vegetables are protected against the mistral by tall hedges of osiers.

Plate 27. Flower cultivation near Grasse (Alpes-Maritimes)

The south-facing slopes below the ramparts of the hill-top village of St Paul are divided by wattle fences into sheltered plots, where flowers and aromatic shrubs are grown for the perfume industry.

Fourme and Laguiole in the Central Massif, and Gerojne-Munster in Lorraine are almost entirely farm-made. In the north there is an increasing output of factory cheese, although much is still farm-produced by individuals; named varieties include Brie, Camembert, Pont l'Eveque, Livarot and Maroilles (Fig. 50). The increase in production which rapidly overtook consumption after 1918 inevitably

Fig. 50. Main cheese-producing districts

Based on the *Atlas de France*, Plate 40 (Paris, 1934),

led to a decrease in prices, accentuated very markedly by the rapid increase in imports. As a result, quota regulations were imposed to restrict imports of butter, cheese and margarine, and a subsidy in 1935 helped to finance the butter export trade. The milk industry is almost wholly unorganized owing to small-scale production, and only in Paris is there any large marketing organization.

Meat. The production of meat is secondary to milk but is not unimportant. The increase in numbers of animals in post-war years has

resulted in a supply sufficient to meet the home demand; some animals were even exported to Italy.

A large proportion of the meat is veal, which is very widely produced because many cows are calved for the sake of their milk; the calves are slaughtered young to save the cost of feeding. There is a certain amount of specialized bullock fattening, especially in the north, where store cattle brought from the Cotentin, the Charolais and Limousin are fattened indoors on sugar-beet pulp and oil-cake. The chief market for fat stock is at La Villette in Paris. Provincial slaughterhouses on a larger scale have been tried, but have failed owing to the small-scale production and the seasonal fattening system which results in long periods of inactivity. The rearing and training of bullocks for draught purposes (Plates 34, 35) and for the plough goes on in most places, but it is a special occupation in the farms of the Central Massif.

Sheep are reared mainly in the departments around and to the north of Paris, in the Central Massif where Aveyron and Lozere are the chief departments, in the Rhone delta and along the Pyrenean foot-hills (Fig. 49). They are also reared on the rougher pastures of the Cotentin, on the saltmarshes of the coast of Brittany and Normandy, and on the drained marshes of Deux-Sevres, Charente and Charente-Inferieure. In the Crau and Camargue districts of the Rhone delta extensive grazing is practised, and flocks are sent to the Alpine districts of Dauphine and Savoy, often by rail, for the summer months (Plate 30). In most of these districts sheep are kept both for wool and mutton. In the Causses, milk of sheep is used for cheese making, and there are over 500 concerns making the well-known Roquefort cheese (Plate 33).

The total number of sheep in France has declined drastically, and in 1938 there were only half as many as in 1900. Among causes to which this decline is attributable are the increase in wages and consequent difficulty of finding shepherds, the disappearance of biennial fallow in the southern part of the country, and low wool prices. As a result there is a large import of sheep, chiefly from Algeria, and of wool.

Pigs. Production is almost entirely unorganized and is devoted to supplying local markets. One or two areas, including Brittany, the Limousin district, Lorraine and Artois, have a certain degree of specialization for ham production, especially where they utilize skimmed milk and whey from the dairies. Apart from those, pigs are kept on a small scale as a secondary source of food almost everywhere but especially by poorer peasants. They are fattened for slaughter in

Fig. 51. Distribution of pigs per 100 ha. of each department, 1938

Fig. 52. Distribution of horses per 1000 ha. of each department, 1938

late autumn and constitute the winter meat supply. Although the quantity sold to the public has increased, over 40% is still consumed on farms. War-time slaughtering between 1914 and 1918 caused a rapid decrease, but since then numbers have increased steadily and the 1938 total slightly exceeded that of 1913 (Fig. 51).

Horses, etc. Despite the extensive development of mechanical traction and the virtual disappearance of horse-drawn vehicles in towns, the horse has held its own since 1918 after the heavy war-time losses. The total number in 1938 was 83·6% of that in 1913. The chief horse-rearing areas are in Brittany, where Finistère has more head (20) per square kilometre than any other department; then come Mayenne and the north-eastern departments (Fig. 52). The animals are bred largely for ploughing.

Mules and asses are used extensively as beasts of burden, there being 135,000 and 85,000 of them respectively in 1938. Mules are used in the south-east and south-west of the country; numbers of donkeys are to be found in Manche and Calvados in the north and in the northern part of the Central Massif, especially in Corrèze.

Other Livestock. Goats and *basse-cour* animals, that is poultry and rabbits, are kept largely as supplements by the small farmers, yet the total value is estimated to be about two-thirds that of the entire wheat crop. One or two goats are often kept to provide milk for those who cannot afford a cow, or maybe a few goats are pastured with the cattle. In some areas to the south of the Loire and in the Rhone valley the goats-milk is made into well-known local cheeses. A number of large farms near Paris produce eggs commercially, but the remainder of the home market is supplied by a very fluctuating yield from the general farms; only about 10% of the eggs that appear in the market are imported.

WORKING POPULATION

In 1931, nearly 7 million people were engaged in agriculture and allied pursuits (Fig. 53), representing approximately 35 % of the working population (Fig. 55); of these just over 3 million were male. The total represents a decrease of over 1·6 million on the 1911 figures, as shown by the following table:

Millions of workers engaged in agriculture

	Male	Female	Total I
1896	5·7	2·8	8·5
1911	5·3	3·2	8·5
1931	3·1	3·8	6·9

(Excluding Alsace and Lorraine)

From P. L. Yates, *Food Production in Western Europe*, p. 283 (London, 1940).

Fig. 53. Distribution of agricultural population per 100 ha. of each department, 1931

Fig. 54. Changes in rural population, 1881-1931, by departments

Statistics from which these figures and also Figs. 55, 56 were drawn were taken from vol. 1, part 3 of the *Recensement general*, 1931 (Paris, 1935).

The large decrease in male agricultural workers is striking; the less marked although considerable total decline is partially compensated by the persistent increase in female labour. This decline has not been uniform over the whole of France. Between 1881 and 1931 the numbers of rural dwellers actually increased in three departments (Fig. 54), but in no case by as much as 5 %. During the same period the most marked decrease was in the departments of Seine, Seine-et-Oise and Alpes-Maritimes where the agricultural population was halved, and in the departments of Rhone, Pas-de-Calais, Meurthe-et-Moselle and Belfort where the decrease was between 40 and 50%. In thirty-six departments the decrease was less than 10 %, notably in Brittany, the Loire valley and the Central Massif. The rural exodus is of long standing; it has been a feature of the mountainous parts since the middle of the last century, but it became more general after 1881. This was due to a variety of causes, including the abandonment to stock of poorer lands, the increase of machinery, the decay of rural industries, the drift to the more attractive work and wages-of the towns, and a birth-rate even lower in rural areas than the generally declining French rate, the result maybe of efforts to reduce the effects of divided inheritance. Yet agriculture is still by far the largest occupational group, and since 1930 the number thus engaged has started to rise again as a result of industrial unemployment. In 1931, 60% of all those employed in agriculture were their own masters either as owners, tenants or *metayers* (see p. 131), while the remaining 40% were labourers or employees in some capacity. Of the latter, 71 % were male and 29 % were female, either workers on the land or farm servants. In 1932, an inquiry into the question of agricultural wages yielded the following results:

Average daily earnings in francs

	1924	1928	1930	1932
All labourers	14-80	20'60	2250	2235
Male labourers		18'94	20'85	20'75
Wagoners		21'56	23'73	23'00
Female labourers		14'20	15'41	15'38
Female servants		13'58	14'74	14'72

The trend of these wages, namely, a steady rise to 1930, then a slight fall, has followed very exactly the trend of wages of other occupational groups. The above figures are averages for the whole country but differ widely in different districts. The proximity of large cities, industrial areas or coalfields necessarily forces agricultural

wages up to meet the industrial competition for available labour. Thus around Paris the average wage per annum in 1937-38 was 14,050 fr., but in Ariège and Hautes-Alpes the figure was only about 4,000 fr. Average pre-1939 French agricultural wages (about 20s. to 25s. per week) compare favourably with Belgium (18s. to 22s.), but very unfavourably with Great Britain (33s. to 40s.).

Most people engaged in agriculture live permanently on the farms where they work, but there is some seasonal movement. This consists partly of a small shifting semi-urban, semi-rural population and partly of a seasonal influx of foreign labourers, but in no case is it great in amount, as the harvest on the characteristic small-holding merely involves the intensive and lengthy labour of all members of the family. The census of 1929 gave a total of over 800,000 men and women of French nationality employed temporarily in agriculture, that is, one-eighth of the total agrarian workers.

In 1929, there were a quarter of a million foreign agricultural workers in France, of whom half were permanently employed. Spaniards, Belgians and Italians from the adjoining countries formed the bulk of this labour, but Poles, chiefly because of their low standard of living and willingness to work for a very small wage, were also numerous. The Poles work mainly in the sugar-beet areas of the north-east, while the Spaniards and Italians are found along the Mediterranean littoral. Full details of the foreign elements in France are contained in Appendix I, pp. 375-92.

LAND TENURE

Farmland in France is cultivated by an owner-occupier, or by a tenant-farmer, or by a *metayer* or 'share-tenant' (Fig. 56). The proportions of these in 1929 were as follows:

	% of holdings	% of area
Owner-occupiers	75	60
Tenants	20	30
<i>Metayers</i>	5	10

From P. L. Yates, *Food Production in Western Europe*, p. 277 (London, 1940).

The owner-occupiers are in the great majority in the south and east, where many departments have 90% of their cultivable land farmed by the owners.

Less than one-third of the total agricultural area of France is cultivated by tenants, although in five departments of the Seine valley more than 70 % is cultivated in this way. In this area farmers and landlords

Plates 28, 29. The hay harvest

In mountain areas the hay crop is a vital part of the farming economy. Plate 28 (above) shows the method of stacking in the Alpine district, where high winds and heavy rain are frequent; Plate 29 shows a mountain farm in the High Vosges of Alsace.

Plate 30. Mountain pasture in Haute-Savoie

These two plates show the contrast between scanty mountain pastures, where sheep roam over wide areas, and rich cultivated *pratnes artificielles*, where restricted grazing by tethered **cattle is part** of a mainly arable farming economy.

co-operate to maintain the farms in the best possible condition. In other parts of France, such as the Sologne, farming is spoilt by sport, and the farmers, who are entitled by law to receive compensation for damage, often live on the compensation.

Metayage, or share-tenancy, is a system whereby the landlord provides the farm, implements and livestock and in return takes half the produce as rent. The landlord may be a landed proprietor, an absentee capitalist, or sometimes a small farmer who has invested in a second holding. There has been a considerable decline in the system in the last hundred years, and only in the departments of Landes and Allier is over half the agricultural area cultivated on this system. Its disadvantages are obvious, for it encourages wasteful cultivation; the tenant is tempted to put in as little and to take out as much as he can; insecurity never makes for good farming. A hard-working single man can earn more as a hired labourer and therefore save enough to buy his own holding in due course. The *metayer* is usually a man who has no capital but can utilize the labour of a large family.

France is a country of smallholders; in 1931, 85·1% of the total number of holdings were less than 10 ha. in area. On the other hand, the remaining 14·9% of the holdings occupy nearly three-quarters of the total area of France (excluding forests).

Size of holding (in hectares)	Number of holdings	% of total	Area of group (hectares)	% of area of France (less forests)
0-1	2,235,405	39·2	1,327,300	2·6
1-10	2,617,558	45·9	11,244,700	22·8
10-50	764,461	13·5		
50-100	52,048	0·9	36,806,800	74·6
Over 100	33,280	0·5		
Total	5,702,752	100	49,378,800	100

The larger holdings are almost entirely in the north-east (Fig. 57) and are devoted to growing sugar beet. Around Soissons, for example, the farms are from 300 to 400 ha. The number of large holdings has decreased during the last 40 years. Some of them were broken up in 1918 in default of heirs, or because of shortage of labour or lack of capital. Holdings of under 2·5 ha. are mainly in the vine areas. The most typical is that of 10-25 ha. with a mixture of horticulture, agriculture and livestock, and this type occupies nearly half the total cultivated area. The smaller grower is favoured by the Wheat Growers'

tax which was imposed in 1938 and which is on a sliding scale, rising sharply with an increase in the area of the holding.

The problem of the prevention of the continual splitting up of the holdings due to the laws of inheritance has given rise to many difficulties. While the principle of the equal division of property among the children had been practised in some districts before 1789,

Fig. 57. Average size of holdings in hectares, 1930, by departments

Napoleon's Civil Code enforced this. Although some children might be bought out, subdivision inevitably increased. In the department of Meuse, for example, one farm of some 30 ha. was divided into about 2,000 'parcels', with each peasant owning twenty or thirty scattered about the whole holding. There have been various attempts, none of them very successful, to meet this problem (pp. 133-4).

LEGISLATION

France is divided for the purposes of agricultural administration into eight regional offices responsible to the Minister of Agriculture. A regional office in turn has the general supervision of the departmental offices within its area. A departmental office is directed by five representatives of the agricultural interests of the department and is managed by trained agriculturalists.

General Policy. The state's agricultural policy has consisted of a spasmodic series of relatively unrelated schemes. Direct subsidies have furthered large schemes such as rural electrification, water supply, road and rail improvements, and the use of fertilizers. There has been a gradual improvement in agricultural inspection, in the registration and compilation of production returns, and in the establishment of agricultural schools, research stations and breeding establishments.

Finance. Almost one-half of the agricultural population are borrowers who obtain credits from the National Mortgage Bank (*credit fonder*) or from the numerous agricultural credit banks, through which direct state loans are made. Other sources are the solicitors and merchants connected with agriculture, and the Joint Stock Banks, together with private organizations such as Peasants' Unions, the Durand Banks and the co-operative banks of Alsace and Lorraine.

Labour. Some effort has been made to improve the lot of the rural worker. Between July 1929 and November 1932 a series of regulations dealing with the accommodation of labourers were passed, and in March 1932 the extension of compulsory family allowances to include agricultural workers was effected. In December 1932, the law enforcing the submission of disputes between employer and employee to a conciliation board (*consdl des prud'hommes*) was applied to agriculture. It had already been operating for industrial disputes. To strengthen the employer's position, a law was passed in February 1932 whereby a former employer might secure damages from the new employer in the event of a labourer breaking a contract to change his job. This helped to check the evil of enticement.

The Size of Holdings. Efforts have also been made to meet the problems of division of property by inheritance. In 1908, a law was enacted which allowed a holding not exceeding the equivalent of £320 to be registered as inalienable. But this figure was much too low and subdivision had already gone too far when it was reached. Regrouping with all its saving of time and efficiency could only really be accomplished by energetic individuals through sale, marriage or

exchange. Clearly, a single person could spoil any scheme by withholding his consent. A state-sponsored regrouping scheme in 1919 helped but little, as a majority vote of a commune was still necessary before the state could take the necessary steps. When a commune agreed to a regrouping scheme, the government paid 80 % of the cost of regrouping as a direct subsidy. As a result, about 600,000 ha., chiefly in the north-east, were regrouped between 1919 and 1929. In 1935, a further act was passed to simplify the procedure for regrouping, but as the initiative is still largely left to the peasants little has been done.

Protection. The state has also pursued a strong policy of protection and encouragement of home agriculture by imposing tariffs and import quotas on a wide variety of agricultural produce, including specified items from particular countries. The problems of over-production at home have been partially tackled by restrictive area quotas and by marketing regulations. The measures adopted towards the two most important commodities, wheat and wine, illustrate the nature of the difficulties and the efforts to overcome them.

In the case of wheat, the outstanding problems in recent years have been those of over-production and of marketing. During 1931 and 1932, imports were still much above average (Fig. 42) in spite of the tariff, while subsequently there were good crops in the years 1932, 1933 and 1938. Efforts were made to limit surpluses by putting growers on an area quota; a 'Wheat Commission' was instituted to dispose of surplus supplies and a minimum selling price was fixed, although in practice it could not be enforced. In 1935, the establishment of new flour mills was forbidden. In 1936, a 'Wheat Office' with local branches was set up to deal with problems of over-production and marketing. Growers were compelled to state the area they had sown and the quantity of wheat harvested; apart from their own consumption, they had to sell to the local co-operative society (Plate 18) or to a licensed dealer. In 1938, the harvest was good and a surplus was the result. To deal with this a tax on producers was imposed.

The great over-production of wine, the obstacles to its export and increasing imports have led to several legislative attempts to meet the situation. In July 1931, it was enacted that no individual or undertaking in France or Algeria owning 10 ha. or harvesting 500 hi. should plant any more vines for 10 years, and fines were imposed on excessively high amounts. The first of these measures was abrogated in the same year as its imposition, but it was re-enacted in July 1933, when for a period of 5 years no increase of vineyard area was to be

Plate 32. Grazing on the Charolais plateau

Plate 33. A cheese cave at Roquefort (Aveyron)

Cheeses, made from sheep's milk, are matured in caves hollowed out of the limestone cliff, on the slopes of which the town of Roquefort is situated.

Plates 34, 35. Ox transport in southern France

Oxen are used extensively as draught animals in many parts of France, notably in Aquitaine. Plate 34 (above) is a scene in St Jean-de-Luz. Plate 35 (below) shows the collection of seaweed on the coast at Hendaye; it is spread on the nearby fields as a fertilizer.

allowed. In July 1932, a system of 'blocage' was put into operation whereby the government was empowered in the event of over-production to fix the amount of wine to be put on the market. In that month no grower harvesting 500 hi. could sell a quantity of wine exceeding two-thirds of his total harvest. Each producer of wine had to register and obtain permits for the sale of produce, while the local Marketing Committee had to release the output as the market could absorb it and thus maintain a minimum price. The whole system hits the larger producers who have to release part of their crop to distilleries at low prices, while the small producers are able to sell at much better prices in the open market. In 1934, cultivators were paid the equivalent of up to £40 per acre for the destruction of their vineyards, but they were not to replant or to grow certain other specified crops, notably tobacco, flax and sugar beet.

Owing to the fact that the majority of growers have holdings less than 1 ha. and are therefore largely untouched by legislation, the schemes to restrict vineyards are ineffective; there was more land under vines in 1938 than at any time since 1913.

French growers have long agitated for a restrictive quota on imported Algerian wine, as the lower costs of production and the large export from the non-wine-drinking Mohammedan population, together with freedom from foreign import duties, affects adversely the home industry. But up to 1936 no legislation had been effected.

FORESTS

Of the total surface area of France about 10½ million ha., that is 19·4%, are forested (Figs. 58, 59). Similar figures for Great Britain are 1¼ million ha. and 5·4% respectively. The woodland is scattered over the whole country, with concentrations partly in certain parts less suitable for cultivation, notably on the bleak exposed uplands and on coarse sandy soils, and partly in preserved state-owned areas. Sixteen departments in 1938 had over 30% of their total area under wood (Fig. 58). In some districts, however, chiefly in the north-west and north-east, forests which once existed on well-drained lowlands have been removed by centuries of intensive cultivation, and woodland now exists only as coppice.

Of the French total of 10½ million ha., 14·4% is state forest, comprising chiefly the afforested areas, and are well maintained by the department of *Eaux et Forêts*, which administers them under a code of forest law.

Another 20-9 % belonging to communes and public bodies are also administered by the same department, while the remainder (647%) is in the hands of private individuals. The proportions of coppice, deciduous and coniferous woods may be seen from the following table:

Forests of France, 1929. Thousands of hectares

Coppice	Deciduous	Coniferous	Total	Recently planted	Total
6,480	1,122	2,777	3,899	292	10,671

Fig. 58. Percentage of area covered with woodland in each department, 1938

The forests may be divided into three main groups, namely, the Mediterranean type in the south-east, the cooler temperate forest of the Atlantic seaboard and hinterland, and the upland forests. Although there is a considerable diversity, areas of certain dominant species may be broadly distinguished.

The major areas of natural woodland will first be considered, then the regions where extensive afforestation has taken place.

*Natural Woodland**(1) The Mediterranean Forests*

These may be divided into two groups, those in Provence and in Languedoc. In the former area, the Aleppo and maritime pines are indigenous, and occur in uniform stands. There are also many exotics and tropical plants in the parks and gardens of the Riviera coast. In

Fig. 59. Distribution of woodland, 1932

Based on the *Atlas de France*, Plate 38 (Paris, 1935).

Languedoc both coniferous and deciduous trees are represented; they include various species of pine, several varieties of evergreen oak and edible chestnut. Other deciduous trees scattered more generally are the lute-tree, some varieties of ash, poplars along the banks of the Rhone, planes, Montpellier maples and alders.

These southern woodlands have been extensively ravaged in this area by cultivation, by past exploitation for shipbuilding, by over-

grazing and by several disastrous fires. In many places a secondary growth has established itself—*garrigue* on limestone and *tnaquis* on siliceous soils. The words themselves are sometimes used to denote the type of country as well as the type of vegetation. *Garrigue* is found mainly to the west of the Rhone in Gard and Herault, on limestone plateaux averaging 150-300 m. but reaching 800 m. in places; they are also found behind Toulon. In *garrigue* the dominant plant is the stunted kerm oak, which grows in thickets, but many other plants thrive—grass, thyme, and more often shrubs like lavender, juniper and cistus (rock-rose). Areas of rock and stony soils bear the arbutus (strawberry tree), laurel and mastic trees, and the asphodel. The majority of these plants are remarkable for their strong scent. Thus *garrigue* country has a rich variety of plants, and belies a first impression of desolation and poverty. All *garrigue* plants possess drought-resisting features such as thorny structures, or leathery, shiny or curled leaves, or long ropts. The drought which limits the growth and type of vegetation results from several factors: a thin soil covering, the permeability of limestone rock, the rapid run-off of rainfall, and the high temperatures and excessive evaporation which prevail during summer when rainfall is lowest.

The *tnaquis* is less varied than the *garrigue*. The country east of the Rhone has more frequent silicious rocks (sands and marls), and here the maritime pine is dominant. These pine forests permit the development of a very dense shrub vegetation of cistus, arbutus and broom. Growing in a less permeable soil, the plants have not such pronounced drought-resisting features as *garrigue* vegetation. The dry nature of the vegetation as a whole and the resin secreted by the pines make the *maquis* particularly liable to the danger of fire.

These two vegetation groups have a complicated history. In Languedoc the *garrigue* is the work of man; the original natural vegetation included many woods of ilex or holm oak, protecting the thin soil which nourished them. Destruction of these valuable trees permitted soil erosion, and on the resulting stony uplands they were followed by thickets of stunted kerm oak. In places where many successive fires have occurred the *garrigue* is replaced by grass steppe, and with overgrazing even this fails to replace itself, and gives way to the final triumph of the asphodel. If, on the contrary, the grass cover is not grazed by animals, it is invaded by thickets of kerm oak, which eventually allow the return of the ilex oak, first in copses, then in forests (though a forest is rarely given time to recover in this way).

The kerm oak was formerly more widespread, and in the eighteenth

century many oaks still survived in the inland parts of the Maures. The progressive removal of these more valuable trees allowed the pine, a latecomer, to take root. The oak has been able to colonize successfully only the limestone country which is unsuited to pines. In the Maures and Esterel massifs, east of the Rhone, abandoned agricultural clearings are invaded first by kerm oaks, but these are in turn stifled by the pines coming back to reconstitute the maquis. Once the maritime pine has secured a foothold it rarely retreats; in spite of fire it replaces itself without human intervention, and the dense closed vegetation of the maquis which follows is able to stifle any oak seeking to re-establish itself in its former territory.

(2) *Temperate Forests*

The undulating plains and hills of the Atlantic seaboard and its hinterland are covered with deciduous trees except where coniferous afforestation has taken place. These temperate forests cover three-quarters of the total area of France and may be conveniently divided into two regional groups, namely:

(a) *Aquitaine and the south-western plain.*

(b) *The north Atlantic coast, the Paris Basin and north-eastern France.*

(a) *Aquitaine and the south-western Plain.* This area is climatically a transition zone between the maritime temperate and Mediterranean regimes, and as a result the vegetation exhibits transitional characteristics. Several species of the southern deciduous trees are found, including the cork oak on the siliceous soils south of the Garonne, the Montpellier maple as far north as Poitiers and Niort, the ilex oak and the pubescent oak in the south, and the pedunculate oak in the lower valleys. Elms and beech occur notably in the forests of Chize and Aulnaye. Conifers, apart from the great afforested Landes (see pp. 141-2), are represented by scattered patches of pines on the hills.

The natural forests on the whole are not extensive, as much of the region is under vineyards, market gardening or permanent grazing.

(b) *The North Atlantic Coast, etc.* The dominant species of this extensive zone are the pedunculate and English oaks, although most of the temperate deciduous trees are represented. Beech trees are common everywhere except in the Loire valley. The fine old domanial forests are largely made up of the two oaks. The mild winters allow the persistence to an unusually northerly latitude of some of the southern evergreen trees. Many conifers have been naturalized, especially on sandy areas such as the Sologne (see p. 142), but

only in rarer places on the uplands, notably in Alsace, are they indigenous.

Some of the largest individual forests other than the afforested areas occur in this region. They include the Forests of Orleans (34,344 ha.) and Fontainebleau (16,855 ha.).

(3) *Upland Forests*

The forests covering the bleaker upland areas are predominantly coniferous, although numerous deciduous trees, mostly beech and ash, occur on the lower slopes. Three main altitudinal zones may be distinguished which vary in height with the latitude of the upland. They comprise a lower zone of firs, pines and beech, a middle zone of larch and Arolla pine, and an upper zone where occur alpine meadows, bushes and isolated dwarf trees. As a rule, however, the tree-line is clear-cut and distinct.

In the Central Massif the main forests, occur between 600 and 800 m. and the upper tree-line is at about 1,200 m. The summits of the uplands range from 1,400 to 1,886 m. and are covered with alpine pasture. Besides a variety of pines, the beech dominates in the Morvan and Montagne Noire, and the sweet chestnut flourishes on the crystalline rocks.

In the Vosges and Jura the tree-line is at 1,200-1,300 m.; beyond this are summit moorlands and pastures devoid of trees. The forests of conifers are extensive on the plateaux from about 700-800 m., while deciduous trees, including maple, plane, mountain ash, mountain elm and beech, are scattered on the lower slopes (Plate 36).

In the Alpine regions the upward tree limit varies considerably according to aspect and district, from about 1,800 to 2,400 m. In the damper northern section the chief tree is *Picea excelsa*, while species of fir cover the valley sides and the lower pre-Alp summits. Below 1,000 m. occurs a mixed coniferous and deciduous woodland, including maple, elm, ash and birch. In the southern section the larch is much more abundant, but the fir and beech are less frequent because of the diminished moisture. The larch, Arolla pine and evergreen alder are often found near the upper limit of tree growth. The woods are less extensive than in the northern section.

The higher forests of the Pyrenees are similar to those of the Alps, the lower ones similar to those of Provence. The tree-line varies between 2,000 and 2,400 m. The cork oak forms extensive evergreen woods on the lowest slopes; higher up, where there is more rain, are dense thickets of kerm oak; chestnuts and beech grow up to 500 m.

with here and there ash and elm; varieties of fir and pine occur up to the tree limit.

Afforestation Policy

The extensive planting of trees as part of a definite state policy has been carried out in many parts of France in both upland and lowland areas. This afforestation has aimed at reducing the country's extensive imports of soft woods and pulp, at making good the forest areas ravaged in the last war, at fixing the sand dunes of the Landes and at combating rain wash and torrent erosion. Conifers are used almost exclusively for artificial plantation as they will grow in almost any physical environment, will reach maturity relatively quickly and will yield a variety of products. The upland areas so planted are chiefly in the Alps and the Central Massif, while outstanding lowland plantations are in the Landes, the Sologne and the *Champagne pouilleuse*.

In the *Alps* afforestation began in 1860 as a defence against soil erosion. By 1929, the state had purchased 189,768 ha. of land and had planted 110,000 ha. of these. A further 89,660 ha. are on schedule to be purchased as future state forests. An additional 32,000 ha. have been planted by individual owners with state help. In the Alps few extensive single state forests have been planted, as no arrondissement or commune is unwooded and afforestation usually takes the form of connecting scattered natural forest.

In the *Central Massif* the most notable work has been done in Aigoual south of the Cevennes, where between 1856 and 1931 the state acquired and planted 13,766 ha. Five-sixths are conifers, but beech, chestnut, ash and some varieties of oak have also been planted. The state delivered 65 million young trees between 1863 and 1933 from the nurseries in the Rhone valley to various communes in the Massif. In the Puy-de-D6me 22,000 ha. were planted between 1843 and 1934. On the Montagne Noire and the plateau of Millevaches (Limousin) future afforestation schemes aim at planting some 90,000 ha. of the total uncultivated area of 110,000 ha.

The *Landes*, which consist of sand dunes, marsh and gravel soils, were very scantily wooded from ancient times. At the end of the eighteenth century there were only a few scattered maritime pines and some dwarf oaks. The physical nature of the terrain made cultivation impossible. In 1783, a few experiments were made with little success, but in 1857 drainage by canals was begun in some places. In 1862, the department of *Eaux et For its* was given charge of the area to combat the invasion of the dunes. A dune wall 8-15 m. high

was built along the coast, about 150 m. behind the highest tide-mark. The hinterland was planted chiefly with maritime pine, and smaller plants were used to fix the terrain. This woodland now covers 956,000 ha. and is by far the largest and most continuous forested area in France (Fig. 59). Owing to a high resin content, the trees are not suitable for pulping; this resin is collected and forms a valuable product (Plate 37). The thinnings are used as pit-props; larger trees when injected with copper sulphate make durable sleepers; mature trees are utilized as constructional timber of all kinds. The necessary drainage has transformed the unhealthy malarious moorland and fen. Population is of course still small, as forestry maintenance does not require many employees, although there are open areas where maize is grown and dairy cattle reared.

The *Sologne* is covered with coarse sand which often lies on clay, and marsh with shallow sheets of water is common. An ancient forest of deciduous woods covered half of it in past years, but by 1800 it had been reduced to one-tenth of its former size. By 1830, however, the forest as a result of planting covered 120,000 ha., of which 72,000 ha. were coniferous. In the winter of 1879 and 1880, a disastrous frost killed most of the maritime pines, so when reafforestation began again other varieties of pine were first used and then Douglas fir. By 1914, the *Sologne* had 170,000 ha. of timber, but nearly half was felled during and immediately after the war of 1914-18. Although afforestation began again, in 1930 the total of 159,000 ha. was still substantially below the pre-war level; another 90,000 ha. are scheduled for planting.

The *Champagne pouilleuse* is over 700,000 ha. in extent; it is little cultivated as the soil is thin and chalky, and the land is utilized almost solely for grazing. Much work has been done by private initiative and many thousands of hectares have been planted with pine, birch, willow and alder, and with oak on the better soils. By 1914, 100,000 ha. had been planted, but these suffered badly owing to excessive felling during the war of 1914-18. Planting now has almost made good the losses.

The *Verdun district* in Lorraine was also terribly devastated during 1914-18. Even the rock was sometimes bared by explosives, and 14,000 ha. of forest were destroyed. By 1938, 12,400 ha. had been reafforested.

THE VICHY REGIME

The harvest of 1938 was good, and large surpluses of wheat and other cereals were stored for possible national emergencies (see p. no). In 1939, the areas under crops showed a small decrease, due largely to the disruption of economic life by the mobilization of September-October 1938. When final mobilization began in August 1939, the harvest was in progress. Although delayed considerably by the immense drain of man-power from the land, it was completed by older men and youths, by women, and in some areas by troops released for the purpose. The season was reasonably good; the areas of crops were usually well below the record high yield of 1938, but in general up to the average. The following table gives the areas and yields of the commodities for which figures are available; the 1938 figures are appended for comparison:

	938		1939	
	Area 1,000 ha.	Yield 1,000 quintals	Area 1,000 ha.	Yield 1,000 quintals
Wheat	5,050	98,010	4,727	78,000
Barley	759	12,907	799	9,980
Rye	631	8,111	648	8,060
Oats	3,245	54,574	3,242	43,540
Maize	340	5,786	329	5,230
Potatoes	1,425	173,145	1,382	150,000
Sugar beet	319	79,800	333	85,000

From official sources.

The armistice of June 1940, with its division into occupied and unoccupied territories, upset the internal agricultural equilibrium of the country. The north, where most of the wheatlands are situated, had to bear the burden of the German army of occupation; the hilly south could not feed itself in normal times. Only in Alsace-Lorraine, which was *de facto* incorporated into the Reich, and in the north-eastern plains did the Germans make any substantial effort to assist agricultural recovery. The agricultural situation was made worse by the large number of men held as prisoners of war, by the slaughtering of livestock for the army of occupation, by the shortage of fertilizers and vine sprays, and by problems of transport and distribution. The bad harvest of 1940, together with the increasingly close blockade, produced a considerable shortage of food during the winter of 1940-1; rationing of bread, sugar, butter, meat, wine, cheese, fats, potatoes, macaroni, rice and pulses was imposed. In spite of efforts by the Vichy government, the food situation continued to be critical,

and the winter of 1941-2 was a hard one for both unoccupied as well as occupied France.

The problem of food supply was naturally much more acute in the towns than in the country, and various schemes attempted to equalize distribution. Farmers were urged to co-operate with the government; quotas were levied, and bonuses paid for prompt supplies; rigorous measures were taken against the 'Black Market'. Illegal trading in foodstuffs became a vital social question in France; it was stated in December 1941 that supplies coming on to the 'Black Market' were as great as or greater than those reaching the legal markets. Large-scale hoarding by peasants was severely punished but with little effect. Malnutrition, especially among children, was very prevalent in the towns; the death-rate rose, and infantile mortality during the first half of 1941 trebled. Trouble culminated in the food riots of January 1942; they occurred chiefly in the southern departments of Hérault and Gard, where even the small rations could not be obtained. Supplementary rations were issued here and elsewhere.

The situation was helped slightly by shiploads of powdered milk, wheat and other supplies from America during 1941, which were allowed through the blockade by Britain on condition that the American Red Cross and American Friends' Service Committee guaranteed that the supplies should not fall into German hands.

The Harvests of 1940-1

Wheat (see pp. 106-10). Over two-thirds of French wheat is produced in the occupied zone. It was estimated that only about 3 million ha. were sown in the autumn of 1939 for the 1940 harvest—over 1½ million ha. less than in the previous year. Destruction of crops by the military operations in the summer of 1940 was not as great as might have been expected, owing to the mobility of the warfare and to the rapid decision. But even so, some wheat was damaged by fighting, and the flight of so many peasant families caused destruction by neglect. Much of what remained was harvested with the help of the German army. To the south, in the unoccupied zone, the harvest was the worst for many years. The total French crop of 1940 was about 42,500,000 quintals—as against the normal 75 million quintals. As a result, in October 1940 strict bread rationing was imposed in both the occupied and unoccupied zones.

In the autumn of 1940 some 4,100,000 ha. were sown, a 30 % increase on the previous year. During the early summer of 1941 small amounts of wheat went from occupied to unoccupied France,

but these were far below what was needed (the deficiency was estimated at 7-8 million quintals in the unoccupied zone), and at the end of May unoccupied France faced extreme hunger. The bread ration was decreased and adulterants were introduced into the flour. The Germans, however, released 2 million quintals out of supplies requisitioned for the army, and this enabled 3 million quintals to be sent by a barter agreement from occupied to unoccupied France; 700,000 quintals were imported from North America, and 145,000 quintals came from America. At the end of June 1941, the bread ration was restored to a normal level (275 grm. or less than 10 oz. per day). The 1941 crop was estimated to be about 65 million quintals, which was more than in 1939 but still well below average.

Other cereals (see pp. 110-13). Nearly all the *oats* are grown in northern France. The harvest of 1940 was poor and totalled only 30 million quintals, or about three-quarters of the 1939 yield. In 1941, the yield improved to about 35 million quintals. The amount used as fodder was drastically reduced, and Germany requisitioned large quantities. The poorer cereals, *millet* and *rye*, which are mainly grown in unoccupied France on the Central Massif, were a little below normal in both years, but they feed only a small proportion of the population. The Germans claimed an increase in the acreage of rye in the occupied zone. Most of the maize comes from unoccupied France. Some 3,400,000 quintals were harvested in 1940, that is, just over half of the previous year's total. No figures are available for the production of *barley*, but here again the Germans claim an increase in 1941 in the occupied zone; this cereal follows the trend of the wheat yield quite closely, so that the 1940 crop may be estimated at 4-5 million quintals, with about half a million more in 1941.

Potatoes (see p. III). The potato crop of 1940 amounted to about 90 million quintals, and in 1941 to about 120 million quintals; both compare unfavourably with the average pre-war yield of about 160 million quintals. In many parts of France potatoes form a staple part of the diet, and a shortage has serious consequences. In September 1941, the government tried to supplement the insufficient rations of bread and meat by as large a ration of potatoes as possible. Compulsory purchase quotas from producers were introduced, and fanners who refused to sell their quota to the government became liable to three years imprisonment. A bonus of 5 fr. per quintal was paid, and urgent appeals for co-operation were made so that requisitions would not be necessary. The Germans distributed small quanti-

ties of potatoes in 1941, ostensibly from their own but more probably from French stocks.

Sugar beet (see pp. 111-13). Almost all the land under sugar beet and all the refineries are in occupied France; the crop suffered considerable damage during the war and there has been a great shortage of sugar, with resultant stringent rationing. In 1940, only 114,000 ha. were harvested from a planted total of 271,000 ha., and the total produced was estimated at 46 million quintals; this figure compared very unfavourably with the 1938 total of nearly 80 million quintals. There was some improvement in 1941, and the output was estimated to be nearly 70 million quintals. The sugar ration in unoccupied France remained at 500 grm. (about 17 oz.) monthly, but that figure was still much below the peace-time consumption.

Wine (see pp. 113-18). The total yield of wine was about 85 million hl. in 1939; in 1940 and 1941, it was estimated to be about 60 and 45 million hl. respectively, which compared unfavourably with the normal average of 70 million hl. Most of the French fine wines, with the exception of those produced in the Burgundy district, come from occupied France. Most French *vin ordinaire* comes from the unoccupied zone, and this output has not been appreciably reduced. It was estimated that 10 million hl., or about one-sixth of the total peace-time output, were requisitioned during 1940 for the German army of occupation. The grapes of the famous vintage areas were grown and processed more casually to produce cheap wines for general consumption.

The industry suffered greatly in 1940 owing to the shortage of skilled labour, and the grape harvest was rarely completed. In 1941, disease was widespread due to the lack of copper sulphate for spraying; in Burgundy, for example, the grapes were almost completely ruined by mildew. On the other hand, vine growing in Alsace has benefited; the area of vineyards in 1940 was 16,000 ha., nearly 1,000 ha. more than in 1939. This development of Alsatian agriculture has been part of German policy. The 30,000 families engaged in viticulture have gained by the elimination of cheaper French wines, which had steadily reduced the Alsatian vine area in pre-war years.

In September 1940, the Vichy government introduced new regulations for vine growers. Every vineyard of more than 5 ha., or producing more than 500 hl., was obliged to grow crops other than vines on one-tenth of its land. Growers producing more than 200 hl. were to keep 20 % of their grape 'must' for turning into sugar, and those producing more than 50 hl. of pure alcohol had to keep the

grape pips for the production of vegetable oil. There was much trouble during 1941 over the distribution of wine, resulting in a clash between the interests of the growers and the government's wine policy. Wine growers asked for higher prices, for more government assistance, and for less requisitioning. General suspicion attributed the shortage of supplies to the sale of requisitioned wine by Germany through neutral firms in Switzerland and Portugal to America. The official explanation was that production for 1940-1 had been abnormally low while consumption had increased, and little had come from Algeria owing to transport difficulties. Severe rationing was introduced at the end of 1941; normal consumers were allowed 1 l. a week and heavy workers 5 l.

Other crops (see pp. 118-20). Efforts were made to increase the cultivation of vegetables generally—of haricots, of soya beans and of other oleaginous plants, of flax, of hemp and of green feeding stuffs. The chief disabilities were shortage of labour, of seed, of fertilizers, and of tools. The only conspicuous increase has been in the case of flax; the area of this crop was 65 % greater in 1941 than in 1938. Otherwise only in Alsace-Lorraine, where the Germans have supplied these wants, was produce up to pre-war standard. The development of agriculture in Alsace-Lorraine was dominated by Germany's needs; the area under tobacco, for example, was maintained by the German tobacco firms which purchased and prepared the entire crop. The winter cultivation of oil seeds (including rape), which had been negligible before the German regime, was increased to 1,900 ha. in 1941 and to 3,500 ha. in 1942. On the other hand, hop cultivation was reduced by 1,000 ha. to avoid competition in the German market.

Livestock (see pp. 120-6)

The majority of *cattle* in 1938 were in the north (see pp. 120-4 and Fig. 48), but large numbers were slaughtered to supply the army of occupation, which drew a large part of its meat from France. Shortage of imported feeding stuffs also caused extensive slaughtering. Unoccupied France in 1938 had only about a quarter of the total French cattle, chiefly dairy herds in the Central Massif, Alps and Jura. It was estimated that even if the total number of milch cows had not declined, the milk output would have been reduced by 15-20 % because of the shortage of oil cake and of other feeding stuffs. Thus there was a great shortage of milk, cheese and butter. In September 1940, cattle were redistributed to compensate areas where herds had been destroyed owing to the war. The German authorities tried to

replace the Lorraine livestock which had been destroyed during hostilities by importing animals from Germany, Holland and Denmark, and in December 1940, 11,000 head of cattle bought from Switzerland and Austria arrived in Strasbourg. Efforts were made in unoccupied France to grow lucerne and roots for fodder. Nevertheless, the total number of cattle in both zones decreased by 25 % between September 1940 and April 1941; in August 1941, it was stated that the herds consisted mainly of young animals which would not be suitable for slaughtering for a long time. By the summer of 1942, the herds of cattle had increased in number compared with April 1942, but the major difficulty continued to be shortage of feeding stuffs.

It was estimated that there was a deficit of only 130,000 *horses* (out of a total of 2½ million) after the armistice, but the German army requisitioned large numbers, and petrol shortage increased the need for horse transport. This deficit was reduced slightly during the winter of 1940-1 by transfers from the army and by imports from Algeria. There is little information about any other livestock, except that in July 1941 the numbers of *pigs* and *sheep* arriving at the Paris market of La Villette were respectively one-quarter and one-half of the total in the same month in 1938. This is probably indicative of peasant hoarding, although the number of pigs in 1941 was some 33-40 % below the pre-war level, due to slaughtering for immediate needs, while sheep were about 15 % below.

The government in September 1941 tried to improve the meat situation by organizing fodder supplies. A plan was drawn up specifying the amounts of barley and oats which each department had to deliver to the departmental agricultural committees for distribution among communes according to the needs of each region. Bonuses were given for quick delivery, and farmers who undertook to carry out government contracts for stock breeding received extra rations of fodder. Nevertheless, the meat ration for January 1942 was cut from 250 grm. (about 8½ oz.) weekly to 180 grm. (about 6oz.) in the towns, and to 125 grm. (about 4oz.) in the country; the extra meat ration for heavy workers remained the same. The cheese ration remained at 50 grm. (under 2 oz.) per week, and all fats remained at 450 grm. (under 1 lb.) per month.

Forests (see pp. 135-42)

After the armistice, the department of *Eaux et Forêts* had to face a large increase in timber consumption. This was due to an almost

complete cessation of timber imports, and to the necessity of using wood in large quantities to be made into charcoal for producer-gas engines, to manufacture cellulose needed by the greatly increased artificial textile industry, to manufacture wooden shoes because of the leather shortage, and as domestic fuel, as well as for all its normal uses of carpentering and furniture making. It was estimated that the amount of wood used directly or indirectly as fuel increased from 14'8 million cu. m. in 1939 to 30 million in 1941, and that the monthly production of charcoal increased from 15,000 tons before the war to 52,000 tons by the end of 1941.

Soon after the armistice, government forestry camps were established to fell timber on a large scale, and a law of August 1940 obliged all forest owners to increase by 50 % the number of trees they normally felled. During 1941 enormous areas of forested land were cleared. But it was increasingly apparent that this was leading to critical deforestation with its resultant evils of floods, soil erosion and avalanches, as well as to grave shortage in the future. Accordingly a law was passed in January 1942 to deal with reafforestation. It provided that from 250,000 to 300,000 ha. should be planted with trees during the next decade, particularly in the Landes, the Montagne Noire and the Millevaches plateau of the Central Massif. Certain districts would be delineated for compulsory planting, and the land-owners would be given the choice either of doing the work themselves with the aid of state subsidies, or of allowing the department of *Eaux et Forêts* to do it.

Labour and Land

An acute shortage of agricultural labour was experienced after the outbreak of war, because the agricultural population was mobilized far more drastically than the industrial. After the armistice the shortage was still worse, as of 1,800,000 prisoners taken by the Germans 1,200,000 were agricultural workers, and few of these have been released.

German Measures. German plans for French agriculture paid less attention to the needs of the French than to the need of a comprehensive plan to increase production through a more intensive exploitation of French resources. France had to supply a large part of European foodstuffs—chiefly fruit, vegetables, wine, wheat, oleaginous plants, flax and hemp. The Germans released prisoners in the occupied zone, and soldiers from the German army were used as farm labourers. The abandoned farms of north-east France were ordered to be

cultivated, and detailed instructions as to which crops were to be grown were issued. German overseers were appointed to farm large tracts of abandoned land, using large-scale mechanization. The Germans also ordered much land in the Maginot area, deliberately left derelict for many years, to be cultivated; it is estimated that about 50,000 out of 150,000 ha. were put under cultivation. Many of the people of Lorraine were assigned to abandoned or uncultivated land with a view to permanent settlement as part of the German effort to develop Alsace-Lorraine. Other measures included credit and loan facilities to assist the financial burdens of reconstruction, and agrarian taxes were lightened pending full recovery. In return for this assistance, the Alsatian farmers were required to produce crops in accordance with German plans.

Vichy Policy. French agricultural policy was dominated by two main objects: first, to supply the country with food and to keep down food prices; and second, to assist the farmers in every way possible and thereby strengthen the economic structure of the country. These policies have been carried out in both zones as far as possible, but to a much less extent in the occupied area. The Vichy government instituted a series of measures to meet the situation in the territory under its control, but most of these, however, have not been implemented.

Attempts were made to stimulate a 'back to the land' movement. All agriculturalists and rural artisans were as far as possible demobilized first. Agricultural Associations assisted in the repatriation of people to their lands, and in September 1940 2 milliard francs were advanced by the Treasury through local branches of the *Credit Agricole* to assist farmers in repairing war damage. Each commune was required to complete within two months an inventory of land left uncultivated for more than two years. The prefect of each department was then authorized to grant such land for a period of nine years to any person of French nationality who could offer adequate guarantees. Preference was to be given to relatives of men killed in the war. No rent was to be paid for the first three years, and after that it was to be only one-half that of similar farms in the same district. Farmers were encouraged to take school leavers, especially those from urban areas, as apprentices; there were 6,000 of these in 1941. The state promised to pay the farmer a subsidy of 900 fr. towards their training. Compulsory land service was instituted for young people between 17 and 21 as a temporary measure. In July 1941, a law was passed requiring the compulsory attendance of all

boys and girls not receiving other education at special agricultural courses. The state also assumed powers to requisition men, preferably urban unemployed with agricultural experience, and to draft them on to the land.

A large government works programme for agriculture was set forth in October 1940. It included schemes of electrification, water supply, drainage and land reclamation, and the building of co-operative factories and dairies. Schemes for land reclamation included the development of the Sologne district, and the reclamation of the Crau district in the Rhone delta by the *Compagnie Nationale du Rhone*, to which subsidies have been paid by the state.

Several measures concerned with the organization of the workers have been effected. In December 1940, an agricultural corporation was outlined, providing for the organization of all farmers and agricultural labourers into local unions within each region (see vol. II, pp. 265-71). These regional organizations were to be coordinated by a national committee. Specialized organizations, insurance and credit societies, and co-operatives, were all to be included within the framework of the agricultural corporation. During the winter of 1941-2 a committee of the *Conseil National* was engaged in drawing up the charter of the Peasant Corporation. The importance of the family holding and the development of modern methods through agricultural unions and co-operatives was emphasized. Official policy aimed at reducing the number of farm labourers by giving them holdings. Subsidies were granted towards the improvement of rural housing.

The Vichy government also made some effort to tackle the problem of divided inheritances (see pp. 132-4), and of the reorganization and regrouping of agricultural holdings. It was clearly impossible to carry out a policy of land resettlement in districts where each farm consisted of many scattered strips. In April 1941, a law was passed whereby the prefect could initiate schemes in any department without the previous necessity of obtaining the consent of a village majority. In each commune strips of land were to be grouped into more compact holdings by a committee appointed by the prefect. No strip after regrouping was to be more than 3 km. away from the farmstead. State help was given to provide new buildings for family holdings. In July 1941, the inheritance code was modified to allow small farms to remain undivided at the request of one of the co-heirs.

As a result of all these efforts, it was stated in May 1941 that nine-tenths of the land abandoned in 1940 had been brought back to

cultivation, and that since July 1940 the state had advanced 200 million francs directly to farmers and a further 200 million francs to Agricultural Credit Societies for reclaiming waste land.

BIBLIOGRAPHICAL NOTE

(1) Statistics, used both in the text and in the compilation of the maps, are given in two French official publications—the extremely detailed *Statistique Agricole Annuelle* (Paris) and the more summary *Annuaire Statistique* (Paris). Statistics relating to the agricultural population are given in detail for 1931 in vol. 1, part 3, of the French census, *Résultats statistiques du recensement général de la population en 1931* (Paris), and in a more summary form for 1936 in vol. 1, part 1, the only section so far published.

(2) General descriptive surveys of French agriculture are given in P. L. Yates, *Food Production in Western Europe* (London, 1940), part iv; in H. Ormsby, *France, A regional and economic geography* (London, 1931); in the *Report on France, Department of Overseas Trade* (H.M.S.O., London, 1934); and in L. Michael, *Agricultural Survey of France* (U.S. Department of Agriculture Bulletin, No. 37, Washington, 1938).

(3) Useful accounts of special regions or of aspects of agriculture are numerous; they include French government pamphlets, notably the *Monographies Agricoles* published by the French *Ministre de l'Agriculture*, the publications of the *Conseil National Economique*, and regional monographs by French writers.

Chapter IV

FISHERIES

Introduction: The Eastern English Channel: Normandy and North Brittany: South Brittany: The Bay of Biscay (south of the Loire): The Mediterranean Coast: Organization and Research: Bibliographical Note

INTRODUCTION

In view of the extensive coastline of France, it is not surprising that the French fishing industry employed in 1937 nearly 70,000 registered boat fishermen (*en bateau*), and about 50,000 part-time shore fishermen. Another 9,000 people were also employed in the preservation of fish and in associated activities; two-thirds of these were women.* Although the fishermen were distributed widely round the coasts, the table on p. 155 shows that the majority lived on the Atlantic coast south of Brest, and that three ports, namely, Concarneau, Lorient and Boulogne, had together nearly one-quarter of the fishermen of France.

The total catch, other than shell-fish, in 1937 was 352,000 metric tons, which compares unfavourably with that of other European countries, as the following table shows:

	1,000 metric tons		1,000 metric tons
Great Britain	1,108	Holland	263
Norway	1,012	Denmark	88
Germany	671	Finland	22
Iceland	322		

Two-thirds of the total French catch by weight is made up of five species offish—cod, herring, sardine, mackerel and tunny; yet 'other products', including finer varieties and shell-fish, form half to three-quarters of the total value, as the following table shows:

	Million francs	
	Total value of all fish	Value of ' other products'
1932	958	663
1933	927	597
1934	893	544
1935	761	516
1936	892	720
1937	1,142	674

* These figures refer to mainland France. Corresponding figures for Corsica and North Africa are included separately in the table on p. 155. It is not possible, however, to isolate the figures of Corsica and North Africa in the tables of total values and weights of individual fish on p. 156.

The proportion of the value of 'other products' was lower in 1937 than for many years, because of the unusually heavy catches of cod, herring and sardines (Fig. 60). This total of 1,142 million francs (to which Corsica and North Africa contributed 88 million francs) was just under one-third the value yielded by the coal mines of France, but it was only one-fiftieth the value of French agricultural produce. The corresponding British fishery figures for 1936 were approximately one-tenth for coal mines and one-twelfth for agriculture.

Fig. 60. Annual French catch of cod, herring, sardine, mackerel and tunny, 1920-37

From *Annuaire Statistique*, 1938 (Paris, 1939).

'Wet fish', as distinct from 'shell-fish', fall into two main classes—pelagic and demersal. The former live in surface waters or at no great depth, and occur in large shoals in the relatively shallow seas on the continental shelf. The more important of these in the French fisheries are the herring, sardine, mackerel and tunny, and the quantities

The source of this and of other tables in this chapter was *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

caught vary tremendously from year to year (Fig. 60). In 1937, the amounts of each were as follows

	Weight metric tons	Value million francs
Herring	64,682	88
Sardine	38,310	125
Mackerel	21,299	62
Tunny	10,658	54
Anchovy	7,547	10
Sprat	2,742	3

Demersal fish live normally at the bottom of the sea; this category includes both flat fish, such as plaice and sole, and free-swimming varieties, notably cod and whiting. Cod is the most important, both by weight and value, but a great variety of other demersal fish is caught. In 1937, the following quantities were landed:

	Weight metric tons	Value million francs
Cod (excluding oil)	65,512	154
Whiting	26,843	71
Skate and ray	14,068	37
Plaice	7,935	29
Sole	1,577	28
Congers	2,846	11
Turbot	1,203	11
Mullet and bass	1,139	11
Eels	1,025	4
Brill	417	4

In addition to these two main categories, the French official returns also include a total of 65,144 metric tons (valued at 200 million francs) of 'other fish', that is, of unclassified *poisson frais*, which are sold unsorted in bulk. Shell-fish, which are hardly comparable by weight, were valued in 1937 at 147 million francs; lobsters comprised 38 million francs, oysters 26 million francs, and shrimps 18 million francs. They formed one-tenth of the total value of French fisheries; the corresponding figure for Britain is only one-thirtieth. To these figures must be added large but unspecified amounts of fish which do not appear in official returns. In the first place, these take account only of fish sold in market, and the amounts consumed by the fishing population itself must be considerable. In the second place, inland and fresh-water fisheries (rivers, lakes and artificial pools) provide an important source of food in country districts.

During the last forty years the French fishing industry has experienced, but to a much less extent, the same centralization and industrialization, which has concentrated the British fishing industry at six main ports. Half the total French catch is landed at four

ports—Boulogne, Lorient, Dieppe and La Rochelle (Fig. 61). The first of these is pre-eminent; over a quarter of French fish are landed there, but even so it handles less than one-third of the annual total of Hull. If the value of fish is considered instead of its weight, Boulogne is still outstanding but less strikingly so, as it is responsible for about one-sixth of the total value.

Fig. 61. Weights of fish landed per annum at French ports, 1937

Based on the *Atlas de France*, Plate 53 (Paris, 1936), with statistics brought up to date from *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

In 1937, there were more than 23,000 fishing craft registered along the French coast, including about 1,500 in Corsica and North Africa. Of this total, only 401 were steam-driven, 11,373 were mechanically driven by Diesel or by auxiliary motors, and 9,711 were sailing boats. The first category, however, amounted to over 92,000 metric tons, or more than one-third of the total fishing tonnage. It is significant

to compare (p. 155) the number of vessels and their total tonnage at Boulogne, Lorient and Fecamp, where most of the large steam trawlers have their base, with ports like S&te, Les Sables d'Olonne or Arcachon. Sete, for example, has more than three times as many craft as Boulogne, but the tonnage of the latter is ten times as great.

The French fishing centres may be conveniently grouped in five areas, as follows:

- (1) The Eastern English Channel.
- (2) Normandy and North Brittany.
- (3) South Brittany.
- (4) The Bay of Biscay (south of the Loire).
- (5) The Mediterranean Sea.

In each stretch of coast the fisheries will first be described, then the important fishing ports.

THE EASTERN ENGLISH CHANNEL

This area is characterized more than any other part of the French coast by the centralization and commercialization of the fishing industry. There are few little villages, such as are typical of Brittany, whose populations earn their livelihood by small-scale and often part-time fishing. Instead, there is a small number of fishing ports able to provide accommodation and fuel facilities for the large mechanized vessels. More than one-third of the total French catch is landed at these ports.

Herring. The entire French catch of herrings, about one-tenth of the European total, is landed along this coast. Herring fishing starts in May in waters to the east of the Shetlands; it has migrated to the seas off Flamborough Head by October, and reaches the Straits of Dover and the Channel in November. Formerly, the typical vessel was the *dundee*, a strongly built sailing boat of from 10 to 60 metric tons, but there is an increasing number of steam or Diesel drifters. These drifters are some 40 m. long, are of about 300 metric tons, and carry a crew of from six to eight. The herring are caught at night by series of drift nets (*raies*), each 50-60 m. long, which form an extended wall of netting kept vertical in the water by buoys and weights, and fastened by a series of ropes to a headline which is attached to the drifting ship. A large amount of herring is caught by trawling in the day time, that is, by dragging along the sea bottom a bag-shaped net kept open by a beam or by wooden trawl boards (*chalut a panneaux*). This takes place off the Shetlands

Plate 39. *Terreneuviers* at St Malo

St Malo is the home base for the *terreneuviers*, which fish for cod off the Grand Banks of Newfoundland. The vessels in the Bassin Duguay-Trouin are decorated with bunting for a religious ceremony before they leave in March for St Pierre and Miquelon.

Plate 40. Fish preserving at Concarneau

Large numbers of women are employed on a part-time basis in the numerous sardine and tunny preserving factories of the town.

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

Towns and Cities: Number and Distribution of Towns; Urban Growth; Conurbations

Note on Family Allowances

Bibliographical Note

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture d'oree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

Fig. 2

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loir (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

Fig. 3. The distribution of population in the Paris Basin, 1931

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

Fig. 4. The distribution of population in northern France, 1931

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

Based on the *Atlas de France*, Plates 74, 75 (Paris, n.d.).

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

Fig. 9

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	- 35	546	176

* Including the Saar territory.

(2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2·0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938

	100.0	100.0	100.0	100.0	100.0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	25.2	21.8	23.3	28.6	32.6
15-49	48.9	53.4	54.0	52.1	51.5
50 +	25.9	24.7	22.7	19.3	14.9
Women: 15-49	48.2	53.3	54.0	52.3	52.6

Of the total population men represent 48.3%; neglecting the foreigners in France, however, men represent only 47.3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations, 1938-9*, p. 44 (Geneva, 1939). For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

*Mortality by Age and Sex: Specific Rates per 10,000
Inhabitants of each Age Group*

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

		M.	F.
France:	1908-13	48.49	52.41
	1920-23	52.19	56.09
	1928-33	54.30	59.02

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 52-4 (Geneva, 1939).

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14·6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0·880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1·0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1·0 for the greater part of this century:

Net Reproduction Rates

1908-13	0930	I	1935	0866
1920-23	0977		1936	088
1925-27	0929		1937	0·87
1928-33	0905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE Neuchatel, reproduced from the French 1 : 80,000 (1901).

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141
Over 10,000 inhabitants	341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30%, Toulouse 17%, and Strasbourg 10%; Nantes (6%) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

*Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas*

Conurbation	Population in 000's	No. of com- munes included	Principal communes
1. Paris	5,500		
2. Marseilles	990	9	Marseilles 914; Aix 43; Aubagne 14
3. Lyons	802	32	Lyons 571; Villeurbanne 81
4. Lille-Roubaix-Tourcoing	731	38	Lille 201; Roubaix 107; Tourcoing 78
5. Bordeaux and suburbs	400	13	Bordeaux 258

23. Brest and suburbs	119		Brest 79
24. Tours and suburbs (banks of Loire and Cher)	117	8	Tours 84
25. Douai industrial group	115	20	Douai 42
26. Amiens and suburbs	107	10	Amiens 94
27. Angers, including Les Ponts-de-Ce, Trelaze and adjoining communes	106	8	Angers 88
28. Dijon and suburbs	105		Dijon 96
29. C6te d'Azur from Cannes to Antibes	102	7	Cannes 49; Antibes 25; Vallauris 10

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

of paying family allowances encouraged the extension of the system to industry, and the shortage of labour in the years 1918-30 provided further incentive to employers to pay these allowances, in order to secure greater stability of labour by the employment of the largest possible number of married men with children. Another motive for the employers was a belief that allowances helped to withdraw family men from interest in the class struggle. To employees the scheme appeared as a means of raising their standard of living. In 1932, some 245 funds covering 1,850,000 employees, and distributing annually 380 million francs, were in operation, and affiliated to a central organization. As the number of private funds grew in these years, the rate of allowances paid to state, departmental and municipal employees increased. Eventually, in 1932, legislation was effected by which all employers were ultimately to subscribe to 'equalization' funds and to grant allowances for dependent children to all French and foreign wage earners and salaried employees.

In 1933 the number of beneficiaries amounted to 5 millions. The programme was extended to more industries, and in 1936 the system was made applicable to all industries and commercial undertakings employing more than ten people, including multiple branch concerns, while in the same year the law was extended to agriculture. The wide extension of the scheme is shown by the fact that the total payments in 1937 were 1,340 million francs, compared with 872 millions in 1936, and were estimated to reach 1,500 million francs for 1938.

Considerable variations were naturally to be found between different areas, both in the rates paid and the subscriptions levied on employers, owing to local differences in wage levels, cost of living, etc. The table on p. 79 illustrates certain rates.

When the scales were revised in 1938, it was provided that the minimum rates should be fixed by the Minister for Labour on the recommendations of the Higher Family Allowances Commission. The age to which allowances were payable for children, apprenticed or pursuing a course of studies, was raised to 17, but after November 1940, no allowance was to be payable for an only child over 5 years old. The new arrangement came into force in April 1939. ,

Machinery for Payment. Funds for the payment of family allowances are obtained entirely by subscriptions from employers. The charges amount to over 2% of the total wages bill in industry. Beginning in 1918, Equalisation Funds (*Caisses de Compensation*) came to be established as a means of regularizing the financial side. Employers contribute to the appropriate funds according to the

number of people they employ, and each fund then distributes the allowances. The Act of 1932 did not create any special machinery for the administration of family allowances, and the existing funds set up by employers were left untouched. Employers not already affiliated to equalization funds were obliged to subscribe. It is important to notice that in order to prevent employers from reducing their liabilities by employing unmarried staff, subscriptions to the funds (*caisses*) are payable for all workers, whether married or single. In 1938 a national compensation fund was established to make grants to local compensation funds, on which the charges were found to be abnormally high. The national fund, which is to be managed by the *Caisse des Depots et Consignations*, is to obtain its resources from subscriptions paid by all the local compensation funds. Until 1932 the subscriptions paid by employers were all voluntary.

Rates of Family Allowances, francs per month

	One child	Two children	Three children	Four children	Each additional child
1936: normal rate	30	70	120	200	80
1936: rate for state employees	52	76	157	196	—
1937: rate in Paris	30	80	200	400	200
1938: rate in Paris	60	160	300	500	200
1938: rates in agriculture	15 to 25	30 to 85	67'5 to 200	110 to 320	27'5 to 120
<i>Rates as percentages:</i>					
1938: rate in Paris as percentage (approx.) of mean wage of 20 skilled trades	4	10	18	30	12
1939: minimum rate at revised scales for the whole of France, as percentage of adult male wage earner	5	15	30	45	15

Conclusion. It is probably too early to form a judgement upon the effectiveness of family allowances in retarding the decline of the birth-rate. The widespread application of the system has been in effect for too short a time to permit of statistically sound conclusions being drawn. As to the funds which were privately operated by firms on a considerable scale soon after 1920, such as the Michelin Company's fund for its employees at Clermont-Ferrand, it is held by some authorities that the higher birth-rate occurring among the beneficiaries of the funds represents inconclusive evidence. The employees are not a typical cross-section of the adult population as

a whole, and some of the employees may have migrated to the Michelin works so as to take advantage of the allowances.

While the payments under the schemes add to the income of parents, the addition is considerably less in amount than the increase in the cost of living incurred through-children. It has been estimated that three children add to the income of a lower grade civil servant an amount equal to only half of what they add to his cost of living. Hence it is considered by some that the scale of family allowances is too small to have any real effect upon the population position. At the most they may have resulted in a slight diminution of the rate of decline in the birth-rate. Such a view is only an opinion, and so far real knowledge cannot be arrived at until statistical investigation of the family allowance system has reached a much more advanced stage.

BIBLIOGRAPHICAL NOTE

(1) *The Census*

Vauban made an estimate of the number of inhabitants of France as long ago as 1700, and other estimates were made in 1762 and 1764. The first organized census was carried out in 1800, and in the next year, 1801, began the series of censuses, at intervals of five years, which has since been continued, except for the census of 1871, which was postponed for one year, and the census of 1916, which was not held.

When the census forms have been collected, they are first utilized to determine the figures of *population legale* in each commune, i.e. the numbers of persons having their habitual residence in the commune. The forms are then tabulated by the *Statistique Generale de la France*, and the entries analysed by category. The figures of *population presente* are obtained at this stage, i.e. the population actually present in each commune on the day of the census. In 1939 the later calculations had not been completed; only the figures of *population legale* or resident population have been published. These figures have been used in the foregoing account. The completion of the census was not expected until 1940. (See also p. 375.)

The published volume is *Resultats Statistiques du Recensement general de la population en 1936* (Statistique Generale, Paris, 1938).

Summarized statements appear in *Annuaire Statistique, 1938* (Paris, 1939).

(2) *Growth of Population*

The official account of population changes is given in *Statistique du mouvement de la population*, vol. xvi, 1936, Part 1 (Statistique Generale, Paris, 1938). Part 1 deals with marriages, divorces, births and deaths.

Chapter II

PARIS

The Site: The Growth of the City: Inner Paris: Greater Paris: Bibliographical Note

THE SITE

The successive stages in the expansion of Paris from its nucleus on an island in the Seine are closely related to the physical features of its site, and are still clearly embodied in its plan. After receiving the waters of the Maine, the Seine, cutting through a line of low heights, begins the first of its loops towards the north. On the southern bank it receives a small tributary, the Bievre, which after flowing east and north is deflected eastwards again by a low spur, the Mont Ste-Genevieve (Fig. 27). In general the relief on the south bank is broken and of moderate elevation. This broken relief imposed limitations upon the city's early development to the south, but farther to the west near the Champ de Mars a portion of the flood plain allowed expansion. Off the Mont Ste-Genevieve, in the centre of the river, lay a number of small islands, now reduced to two—lie de la Cite and lie St Louis (Plate 10). These islands, and the numerous side branches which originally characterized this stretch of the river, due perhaps to the decrease in the slope of the bed, formed a complicated pattern, but it happened that a line from the southern height across the present lie de la Cite avoided most of the obstacles.

On the north bank, the relief is in contrast to that of the south. A semicircle of heights leaves the river at Charonne on the east, and runs through Menilmontant, Belleville, Montmartre, and Chaillot, returning to the river at Passy. These heights mark the northern slopes of the Quaternary course of the Seine, the loop of which was much more pronounced than that of the present river (Fig. 27). Probably owing to changes in the course of the Marne, which increased the velocity of the Seine, the latter cut off the extremity of this loop to occupy its present course. Thus the area immediately north of the Seine is a segment of a meander plain, originally sloping not to the Seine, which cut a narrow bed through it, but towards the older course. In the early history of the city this was occupied in its western portion by a stream flowing from Menilmontant, and in its eastern end by an area of marshland, Le Marais.

The north bank therefore afforded ample space for expansion, and the growth of Paris in this direction has been closely related to this abandoned river course. At one period, portions of it were incorporated as a moat forming part of the city's fortifications. At times, too, it has proved a source of anxiety to the city engineers, for the Seine in flood has occasionally attempted to reoccupy its former bed. Thus in the floods of 1910 subsoil penetration by this channel flooded large areas round the Gare St Lazare. The original relief, however, has been largely hidden by drainage, by newly-made ground, and by buildings. It is important to note also that the northern ring of heights is not continuous: Montmartre is isolated by gaps to east and west, the former being especially important as it affords an easy line of communication northwards.

The significant features of the site therefore are the approach of the southern hills to the river, the islands in the river bed reducing the difficulty of bridging, the open plain on the north bank, and the breeches in the northern heights. The three main areas—southern heights, islands, and northern plain—have persisted from early days as subdivisions with distinct characteristics associated respectively with Universite, Cite, and Ville.

THE GROWTH OF THE CITY

The Early Medieval City

Before the Roman occupation of Gaul, the Ile de la Cite was the site of a settlement, Lutetia, the centre of a Gaulish tribe, the Parisii. By this time the Seine had been bridged and the island was close to an intersection of routes, a south-to-north land route and an east-to-west river way. Roman observers remarked upon the busy boat traffic on the river. Under Roman administration the principal section of the town was laid out on the southern bank, on the slopes of the Mont Ste-Genevieve. A Roman road from Chartres ran northwards across the lie de la Cite and up through the Montmartre-Belleville gap; on the north bank it was joined by another road descending the valley westwards from Melun, and it was around this junction that commerce was increasingly to centre.

During the first centuries of the Middle Ages however progress was slow. In the disturbed times following the Roman withdrawal and the Frankish advance, when the Roman town on the south bank was destroyed, settlement was chiefly confined to the island with two bridgeheads north and south of the river. Under the Merovingians,

in the fifth and sixth centuries, order was re-established, and with the expanding influence of the Church the elements of civilized life gradually returned. During the reign of Clovis, the basilica of SS. Peter and Paul was built on the southern quarter, and other churches soon followed (St Benoit, St Severin). Settlement on the outskirts was encouraged by ecclesiastical foundations, the abbey of St Germain TAuxerrois on the north bank, and of St Germain des Pres on a former left bank island below the city limits. The surrounding forests were gradually cleared during the ninth century, and with the revival of trade the value of the position of Paris became recognized, by none more clearly than the early rulers of the House of Capet. Indeed, it was their great achievement to establish Paris as the undisputed capital of France. By their efforts the advance of the Norsemen was stayed at the city walls after a siege during which the southern quarter was again destroyed, and their royal duchy, extending north and south of the Seine and conveniently linked by Paris, was welded together to become the foundation of the kingdom of France.*

It was to the centralizing policy of the French monarchy more than to any combination of geographical factors that the city's predominance and extraordinary growth were due. As the seat of the central government, the courts of law, and the great university of the Middle Ages, Paris drew to itself, with increasing attractive power, first the professions and trades necessary to sustain their needs, and later an industrial population to meet the demand for goods as close to the market as possible. Thus the development of Paris has been from an administrative centre to a great commercial market, and finally to an industrial concentration. The development of a planned system of roads, of canals, and of railways merely tightened the hold of Paris on the country.

The effect of this Capetian centralizing policy was soon visible in the development of the city, which during the twelfth century assumed its characteristic tripartite form. The *lie de la Cite* was the centre of royal and ecclesiastical administration. In the middle of the century the building of the new cathedral of Notre Dame was begun, and the church schools formerly grouped around it moved across to the south bank where, around the theological college founded by Robert de Sorbon in 1253, the University and its quarter crystallized. Here gathered, besides masters and scholars, the attendant scribes, followed later by the printers.

On the north bank was the 'Ville,' the predominantly commercial

* For the historical background, see vol. 11, pp. 46 et seq., of this Handbook.

Plate 10. Paris: The He de la Cite

On the island is the Palais de Justice in the foreground, with Notre-Dame Cathedral and the Hotel Dieu near the other end. There is a clear contrast between the congested streets and buildings of the 'Quartier Latin' on the left bank (on right of picture), and the more elegant tree-lined avenues and open spaces of the right bank, where the Hotel de Ville is prominent.

Plate 11. Factories at Billancourt, Paris
The great Renault works extend over a large area and have even spread to the island in the Seine.

quarter; upstream from the bridges, along the creeks and quays, grew the first 'ports' of Paris. The importance of the river traffic, which carried down to the city the wines and timber of the upper Seine basin, is seen from the growing influence of the 'Corporation of water merchants', the head of which became during the thirteenth century the chief civil officer of the municipality. The principal 'port' was on the site now occupied by the Place du Chatelet, near the Hotel-de-Ville, and close to the *croisee de Paris*, the junction of the main routes. Between the water front and the roads were established large markets, an area still partly occupied by the Halles Centrales.

The City Walls

It was around this threefold area that Philip Augustus between 1180 and 1210 built the first city wall (Fig. 27). From the eastern limit of the trading quarter on the north bank it ran in a rough semicircle, the maximum distance from the river being about 800 m., to rest in the west on the recently built fortress of the Louvre. On the south bank it enclosed the Mont Ste-Genevieve, forming the limit of the city in this direction until well into the seventeenth century. The next period of growth was therefore on the north bank, at first eastwards until the marshland along the old course of the river was reached. This marsh was gradually drained and occupied by market gardens to supply the growing city, until it was built over in the eighteenth century. The second important line of fortifications, built by Charles V about 1370, began at the Bastille and incorporated the Louvre on the west. Within the old limits the population had been growing rapidly: on a basis of a census of hearths taken in 1329 it is estimated that the population was then about a quarter of a million, a remarkable figure for the period. The new walls, however, included considerable areas of open land sufficient for some time to absorb growth which at first slackened owing to disturbed political conditions, although by the seventeenth century the city was spreading rapidly beyond the walls, mainly northwards, despite successive royal edicts establishing forbidden zones. These were partly prompted by fears of inability to feed so large a concentration, hence the preservation of the gardens of Le Marais and the attention to the water supply. The city was dependent largely upon water from the Seine, pumped directly from the river at La Samaritaine and the Pont Notre Dame. In the middle of the fourteenth century the population was nearing half a million, a stage in its development which was not materially passed until the industrial era.

The next extension of boundaries had a fiscal rather than a military reason; to facilitate the collection of the *octroi* a wall, the 'Mur des Fermiers-Generaux', was built between 1784 and 1791, with a radius some 1,500 m. larger than that of the preceding wall. This carried the northern limits of the city to the line of the old river course and

Fig. 27. The site and growth of Paris

Based on G. R. Crone, 'The site and growth of Paris', *Geographical Journal*, vol. xcvi, p. 37 (London, 1941). For the work of Philip Augustus, see vol. 11, p. 49 of this Handbook.

the foot of the northern heights. It enclosed the faubourgs which had grown up along the radiating routes and much open land, especially on the south bank. Portions of the old ramparts became the line of the great or inner boulevards.

Throughout the eighteenth century the population did not rise above half a million, but with the progress of the industrial revolution the city again pressed upon its limits. By 1841 the inhabitants

numbered 935,000, and it was then decided for military reasons to fortify a much extended area. The *enceinte* was thrown along the northern heights beyond Belleville and Montmartre and southwards towards Gentilly and Issy. This brought within the limits of Paris a number of considerable towns, for Belleville had at that time a population of 57,000 people, and Montmartre 35,000. With the incorporation in 1861 of the communes thus enclosed, the population of Paris rose to 1,690,000. The wall of the Farmers-General then became the line of the outer boulevards.

Fig. 28. The built-up area in 1839

Based on *Carte des Environs de Paris*, drawn in 1839 at the Depot Generale de la Guerre, under the direction of Lieutenant-General B. Pelet.

Industrial Growth

With industrialization and improved communications, the activities of the population also began to change markedly. Formerly, the occupation of the Parisian workers, apart from the predominating official and commercial classes, had lain mainly in trades requiring traditional skill and taste rather than an abundant supply of raw material. With the building of canals and railways, supplies of materials

for heavier industries, particularly coal and iron, became available and industry was freed from its dependence upon the river front. In the twenties there was an epoch of canal building. The Canal St Denis and the Canal St Martin were followed a few years later by the Canal de l'Ourcq. With the building of the canals the prosperity of Paris became even more closely linked to waterborne traffic, which was handled at various quays and basins along the river and the canal system, while river ports have developed up and down stream from Paris to serve the industrial suburbs, e.g. at Ivry, St Ouen, St Denis, and Gennevilliers.*

Close on the canals followed the railways. On the north bank the gaps east and west of Montmartre served as convenient routes ending at the great termini of the Gares de PEst, du Nord, and St Lazare, placed near the outer boulevards. The area enclosed in 1841 made much land available for building, and around the canal basins and stations gathered warehouses and slaughterhouses, railway goods yards and repair shops, factories and gasworks, with tenements in the neighbouring quarters to house the workers. †

While Paris was thus expanding and its industries growing, wide changes were also being made to the plan of the city. These were initiated by Napoleon III, partly on aesthetic and partly on military grounds, and the work of reconstruction was entrusted to Baron Haussmann between 1854 and 1869. Narrow streets and congested areas gave place to wide boulevards and squares (Place de l'Etoile, Boulevard St Michel); parks and gardens were laid out (Bois de Boulogne); public buildings such as the Opera were erected; and the ring of outer boulevards was built on the line of the wall of the Farmers-General. This work was naturally costly, and Haussmann met with much opposition: it is to his persistence and the emperor's support that modern Paris owes its spaciousness and its vistas.

As a result of its industrial development, the population of Paris grew rapidly after 1861, increasing by 25 % in the next twenty years. From 1881 to 1901 the rate of increase declined to about 20%, and with the beginning of this century the period of rapid expansion was approaching its close. The population reached a maximum in 1921 with a figure of 2,906,000, but this represented an increase in the preceding twenty years of 7 % only. The war of 1914-18 no doubt had

* The waterways serving Paris are more fully dealt with in vol. iv, chapter vi, of this Handbook.

† The railways serving Paris are dealt with more fully in vol. iv, chapter iv, of this Handbook.

some influence on this slowing up of the city's growth, but decline had already set in before 1911. Since 1921, the population has fallen to 2,891,000 in 1931, and to 2,830,000 in 1936, a decline of roughly 2½%. To sum up: the net result of a century of growth, 1839-1939, can be seen by comparing Figs. 28 and 29.

Fig. 29. The built-up area in 1939

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 2 (Paris, 1934), and air photographs.

Water Supply

The growth of the city has been accompanied by improvements in the water supply. Until the nineteenth century, the domestic water of Paris was drawn mainly from wells or from the Seine. The latter was raised by pumps, the first of which, La Samaritaine, was set up at the Pont Neuf in the reign of Henry IV. Later in the seventeenth century other pumps were erected at Notre Dame and at Marly for the supply of Versailles. The public fountains were, however, supplied to some extent with water from other sources, e.g. the Belleville aqueduct, said to date from the fourteenth century, and the Arcueil aqueduct, restored by Marie de Medici. These supplies were

inadequate for the expanding city, and the first step taken to obtain water from a distance was the construction in 1822 of the Canal de l'Ourcq, which for some years served as an aqueduct as well as a navigable canal. About the same time, attempts were made to utilize artesian supplies at Grenelle and elsewhere, but owing to technical difficulties these wells were abandoned. It was not until the Second Empire that the problem was solved by the engineer Belgrand, who laid the foundations of the present system. The earlier superficial supplies, were now used for public and industrial purposes, while domestic water was obtained by tapping adequate and pure supplies at the sources of distant streams; this water was led through aqueducts or underground conduits to reservoirs on the suburban heights. The first to be completed, in 1865, was that from the sources of the Dhuis, a tributary of the Marne, which carries water 114 km. to a reservoir at Menilmontant. Later, water was similarly brought from the Vanne, an affluent of the Yonne, to Montsouris (173 km.), and from the Arvre, a tributary of the Eure, to St Cloud (120 km.). More recently, Supplies for the Montsouris reservoir have been obtained from the Loing and Lunain (73 km.), and the Vanne supplies have been augmented by the Voulzie aqueduct, completed in 1925.

The water from these sources amounts to about 450,000 cu.m. per day, which is still inadequate to meet the demand, especially in summer. Some 300,000 cu.m. have therefore to be pumped from the Seine and Marne, filtered and sterilized at Saint-Maur and Ivry, and either mixed with the other water or retained in separate reservoirs. In addition, very large quantities of river water, distributed through a separate system, are used by public authorities for street cleansing, etc., and by factories, and the maximum amount that can be removed from the rivers is being approached. There have been proposals therefore to seek further supplies from the water-bearing beds in the valley of the Loire, 200 km. south of Paris, which, it has been estimated, could yield 1 million cu.m. a day. It is probable, however, that the cost of the water thus obtained would be greater than that of water from the Seine after it has been filtered and pumped up to the reservoirs. Technical improvements have now made it possible to use artesian water in the outer districts: e.g. the artesian well sunk at Aulnay-sous-Bois in 1933 to a depth of 831 m. yields 5,000 cu.m. a day for the north-western districts.

INNER PARIS

Inner Paris: Population Changes since 1841

The slowing up of the rate of increase and eventual decline in the population of Paris was accompanied by a very rapid growth in the surrounding region, but before dealing with Greater Paris something

Fig. 30

Fig. 31

Fig. 30. The decline of population in the centre of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The decline in the central districts has been most marked in those which lie to the north of the river, particularly in the arrondissement of La Bourse and in the quartier of Les Halles.

Fig. 31. The growth of population in the outer districts of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The outer arrondissements of the city have increased considerably in population; more especially those which lie to the south. These areas have a number of light industries, and they also contain the homes of large numbers of the people who work in the heart of the city, many of whom have been displaced from the centre in recent decades. Outstanding among the districts of rapid increase are Clignancourt to the north, Buttes Chaumont and Menilmontant to the east, Vaugirard and Petit Montrouge to the south, and Auteuil and Passy to the south-west.

should be said of the distribution of population within the city limits. The city, that is, the area within the *enceinte* of 1841, plus the narrow military zone around it, the Bois de Boulogne, and the Bois de Vincennes, has an area of approximately 78 sq. km. In comparison with other great cities, this is relatively small, and the average density of population (37,000 per sq. km. in 1931) is consequently high. The administrative County of London, for example, has an area almost four times as great. Towards the end of the century, in 1896, the

corresponding figure was 32,000, so that the increase in density between 1896 and 1931 was 15 %. But this increase was not uniform over the whole city.

Two tendencies have been at work. With the continually increasing scale of operations, the heavier industries which had at first tended to concentrate in the northern quarters of the city began to move outwards into the open country, where ample and cheap sites, well placed for river and rail communications, were available. As a result, the Paris region became one of the most important in France for chemical, textile, and engineering works, and in 1931, 20% of French skilled workers were resident in the departments of Seine and Seine-et-Oise. Another tendency has been the so-called ⁱ flight from the centre'. The increasing demand for sites for administrative and commercial offices, banks, large stores, etc. in the centre has led to a rise in land values, and the consequent demolition of old residential property. Moreover, the improved facilities for travel to and from the suburbs have enabled city workers to live at a distance from their work. The insanitary condition of the former densely peopled quarters has also led the municipality to demolish properties and to move the inhabitants to new quarters on the edge of the city. The result of these developments has therefore been to reduce considerably the density of the resident population in the centre of the city, to increase that of the quarters on the periphery, and to bring into existence in the Greater Paris region large industrial and dormitory towns (Figs. 31-33).

Inner Paris: Distribution of Population

Comparing the distributions of 1896 and 1931, it is apparent that Paris can be regarded as composed approximately of three zones with individual characteristics, in which varying tendencies are visible.

The centre of the city, comprising the first seven arrondissements, covers the three historic components of *cite*, *ville*, and *universite*. The most densely populated of these arrondissements is the Temple, with over 50,000 inhabitants per sq. km., followed by L'Hotel de Ville and La Bourse, all on the north bank with 25,000-50,000 per sq. km. These constitute the financial and commercial district, with subsidiary activities such as newspaper production, and have all declined in resident population. This is particularly noticeable in La Bourse, where three of the quarters decreased by more than 35 % between 1896 and 1931. It is significant, as showing the piecemeal nature of this outward movement, that the fourth quarter remains one of the most densely

populated in the city, Bonne-Nouvelle with 101,500 per sq. km., and that the St Gervais quarter of the Hotel de Ville had in 1931 the exceptionally high density of 106,900 per sq. km. The fourth of these arrondissements on the north bank is the Louvre, with a lower density of 10,000-25,000 per sq. km. This includes the central markets (Les Halles), and also an area lying between the Champs-Elysees and L'Opera, which is the centre of 'haute couture', i.e. the production of 'Paris fashions'. The reason for this localization probably lies in the former focusing of court life around the Louvre and the Tuileries. The more popular 'grands magasins' lie between this point and the commercial area. Decline in population has also been very marked here, that of the quarter of the Halles having exceeded 50%. This area is also the home of highly skilled craftsmen, working on a small scale, e.g. costumiers, tailors, gold- and silversmiths, jewellers, and leather workers, who supply the demand for luxury articles.

The portion of the central area south of the river comprises the Pantheon, Luxembourg, and Palais Bourbon. The first two, corresponding to the University and 'quartier latin', had densities of 25,000-50,000 per sq. km.; the third, containing the homes of the aristocratic families of the Faubourg St Germain, of the diplomats in the shadow of the Quai d'Orsay, and of retired officials, is less heavily populated (10,000-25,000 per sq. km.).

The second zone, on the north bank, includes the arrondissements of L'Opera, L'Enclos-St Laurent, and Popincourt. This is the area of the Gares St Lazare, du Nord, and de l'Est, of the Canal St Martin, and consequently of commercial and manufacturing activity. Thus L'Opera and Popincourt were two of the three arrondissements which still retained in 1931 densities greater than 50,000 per sq. km. The quartier Rochechouart of L'Opera had the high density of 90,300 per sq. km., and was the sole area in this zone which increased during this period. The decline elsewhere was largely due to the spread of business houses and luxury shops in this direction from the centre: as a result, one district adjacent to La Bourse, the 'quartier de la Chaussee d'Antin', had decreased by more than 50%. The decline was less marked in Popincourt, which is largely a district of workers' tenements, with a large foreign element.

The third zone is that of the outer ring of arrondissements, mainly industrial and working-class areas, e.g. Batignolles, Montmartre, Chaumont, and Vaugirard, with a density in general between 25,000 and 50,000 per sq. km. This ring is broken at one point in the south-west by wealthier residential districts on the heights of Passy. Save

in a few minor districts, the population of this zone increased markedly since 1896. High increases of over 150% occurred in the manufacturing area of Vaugirard, and in Passy; several other quartiers increased by 65-120%. Though not the scene of heavy industries

Fig. 32. The density of population in the department of the Seine, 1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 20 (Paris, 1934).

In the city itself the greatest densities are found to the north of the Seine. In the remainder of the department the principal area of high density lies to the north-west on both sides of the Seine—at Neuilly, Clichy, Puteaux, Courbevoie and Colombes. This distribution largely reflects the distribution of industry in Greater Paris. B, Bois de Boulogne; W, Bois de Vincennes.

similar to those of Greater Paris, these exterior arrondissements have a variety of industries, such as the furniture factories of the Faubourg St Antoine (Batignolles), the boot factories of Belleville, and the light metal works of Charonne, apart from those more directly associated with the railways. These areas are also the homes of those displaced from the centre who work daily in the city and the west.

GREATER PARIS

Growth of Population

The boundaries which should be assigned to Greater Paris are not easy to determine precisely. During discussions in 1932 on future

Fig. 33. The growth of population in outer Paris, i.e. the department of the Seine outside the city limits, 1876-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 22 (Paris, 1934).

While the increase has been fairly general, it has been most marked to the north and north-east, and in some areas to the south. It will be noted that these areas lie mostly away from the city limits, for by 1876 the communes immediately adjoining Paris had already begun to experience a growth of population spreading outward from the city. These more remote communes, such as Gennevilliers and Colombes to the north-west, La Corneuve, Le Bourget, Drancy, Aubervilliers, Pantin, Bobigny and Villemomble to the north-east, and Gentilly, Villejuif and Sceaux to the south, had very small populations in 1876, and with the spread of industry in recent decades their growth has appeared all the more striking.

growth it was declared to consist of the department of the Seine, those communes of Seine-et-Oise and Seine-et-Marne within a radius of 35 km. of Paris, and a large proportion of L'Oise, forming an area

Fig. 34

of approximately 5,000 sq. km. with a population of 6,300,000. This deliberately included areas not then dominated by Paris: but whatever the exact boundaries, there is no doubt that the whole of the department of the Seine falls within Greater Paris, and recent censuses show how rapid has been the growth of its population. In 1881 the department, excluding Paris, had 530,000 inhabitants: this figure, by 1901, had nearly doubled (956,000), and trebled by 1921 (1,506,000); by 1936 it was 2,133,000, comparable with that of the city itself, with an average density of approximately 5,300 per sq. km. (Figs. 32, 33).

Development in these outer regions has spread along the lines of communications, absorbing long-established towns, and generally repeating the characteristics of the city's quarters thus extended—industrial areas on the lower, more accessible land, and residential suburbs on the higher. Four industrial areas are conspicuous : * (1) the north and north-eastern, comprising St Denis, St Ouen, Aubervilliers, and Pantin; (2) the west and north-western, spread along the winding valley of the lower Seine (Fig. 34); (3) the south-eastern, in the upper Seine valley as far as Choisy and extending west to the valley of the Bievre; and (4) the south and south-western, adjoining the city limits in the Gentilly, Vanves, and Arcueil areas, and extending westwards to Issy-les-Moulineaux.

North and North-eastern Industrial Suburbs. The first of these is of considerable importance. The basis of its development has been the St Denis canal, which, via the Canal de TOurcq, brings Pantin on the east within the area. The important industries of St Denis produce locomotives and wagons, engineering and electrical equipment, acids, fertilizers, soaps, etc., and along the Seine ships and barges are built. St Ouen to the south has a number of very diversified industries, generally of a lighter character—copper and aluminium

* For details of industry, see pp. 177-9.

Fig. 34. The industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The line of the 1841-5 fortifications is represented by the circular line of railway, except to the east where it is marked by a belt devoid of factories. Thus to the north, north-west and south-west most of the factories lie outside the city limits, while to the east and south they lie more within them. It is clear that the location of the larger factories is much more closely related to the river and to the railways than to the canals. The Port de Gennevilliers is a barge port of recent construction, in which the two existing docks will be followed by others, the whole system being designed to serve the growing industries of Colombes, Gennevilliers and Argenteuil.

goods, tinned foods, furniture and pianos, gloves from skins. The industries of Aubervilliers, La Courneuve, and Pantin are predominantly chemical, ranging from oil refining to perfumes and toilet articles, while the by-products of the Villette slaughterhouses are used for the manufacture of tallow, margarine and leather. In these districts the available labour has attracted many minor factories,

Fig. 35. The metal industries of Greater Paris, 1939

These include mechanical and constructional engineering and a variety of metal manufactures. The majority of these factories lie to the east and south.

producing, for example, glass and pottery at St Denis, and sewing cotton and tobacco at Pantin. These five communes form a block of over 240,000 inhabitants, which increased between 1921 and 1936 by approximately 15%, despite a marked decline in the depression following 1931. This manufacturing area is spreading north-eastwards towards the rail and air centre of Le Bourget, competing for the available land with the builders of housing estates, who have been particularly active around Drancy (Figs. 28, 35).

West and North-western Industrial Suburbs. The second great industrial group is in the west and north-west, established along the valley of the Seine. Immediately west of Paris is the centre of the French motor and aircraft industries, with the Citroen works at Grenelle and the Renault at Boulogne-Billancourt (Plate II). Here

Fig. 36. The electrical, automobile and aircraft industries of Greater Paris, 1939 Based on (1) *Carte Industrielle de la Région Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The concentration of these industries to the north-west and south-west is clear. Figs. 35 and 36 are complementary, and show between them all the metal-using industries. Fig. 35 shows mainly old-established industries; Fig. 36 shows newer industries.

expansion has been rapid, the population of the latter commune having increased from 68,000 in 1921 to 97,000 in 1936. Farther downstream, on both sides of the valley, extends a string of industrial concentrations combining the engineering and manufacturing activities of their neighbours to the north and south: Suresnes, Puteaux (armaments), Courbevoie, Levallois-Perret (motors and aircraft), Clichy (gas works and oil refineries along the river), and Asnteres (chemicals

and foodstuffs). The population of this zone exceeds 380,000, having increased by approximately 20 % between 1921 and 1936. Expansion has progressed in the loop of the Seine towards Argenteuil, notably around Gennevilliers, where there is a large electric power station fed by water- and rail-borne coal. Interlaced with these and standing on the higher ground are residential suburbs, e.g. Neuilly, Nanterre and Colombes (Fig. 36).

South-eastern Industrial Suburbs. The industrial areas are repeated on a somewhat smaller scale in the south-east along the Seine valley through Ivry and Vitry, where there are large power stations and gasworks. Vitry, however, still continues to grow flowers for the city markets, whilst Choisy manufactures linoleum, paper and china. Here live a population of some 120,000.

South and South-western Industrial Suburbs. Another industrial belt extends to the west, skirting the city limits as far as the Seine; its features are the tanneries and laundries in the valley of the Bievre around Gentilly which perpetuate the early use made of its waters, and Issy-les-Moulineaux, with its power stations, munition and cement works, breweries, and tobacco factories. This sector has a population of over 200,000. From its western end a series of small towns continue southwards over the broken plateau, and house thousands who work daily in Paris; these towns, interspersed with market gardens, carry the boundaries of Greater Paris beyond Sceaux. The recent electrification of the railway line serving this area may be expected to stimulate the further development of dormitory estates.*

Eastern Residential Suburbs. In this circuit of Paris one sector has so far been omitted, the eastern, which has become the predominantly residential area of the outskirts, beyond the factories along the eastern border of the city. Extending over the gentle and formerly wooded hills north of the Marne as far as the boundary of the department are numerous residential towns such as Vincennes, Montreuil, and Fontenay-sous-Bois, with islands of orchards, vegetable and flower gardens, scarcely touched by industrial development. Nearly a quarter of a million people have their homes in this sector of Greater Paris. Similar expansion has taken place along the valley of the Marne, the tide of building progressing from one loop of the river to the next as far as Nogent. The peninsula between the Seine and the Marne is occupied by the working-class suburb around Alfortville comprising some 75,000 inhabitants. In the first great loop of the Marne is the garden city of St Maur (57,000); in the next Champigny (27,500),

* See vol. iv, chapter iv, of this Handbook.

and again in the next Nogent and Le Perreux (together 45,000), developments all consequent on the breaking up of large estates towards the end of the last century. Market gardening is still carried on to some extent, but except around Alfortville and Maisons-Alfort there has so far been little industrial development.

Regional Planning

This development of the Paris region has been haphazard and unco-ordinated. Factories and housing estates are intermingled: the new quarters of the expanding towns are often unprovided with adequate roads, drainage, or water supply: valuable agricultural land has been built over: and natural amenities have been destroyed. This has resulted from the lack of a central authority, the constituent communes being largely independent and without the means to develop in an orderly way. In 1932 a law prescribing a 'projet d'aménagement' for the whole region was promulgated. A general directing plan was drawn up and presented in 1934, with which the local schemes were to conform. It covered the lay-out of the main roads, open spaces, the use of the land and the regulation of buildings, public services, and the protection of sites. The scheme for communications provided for five radial motor roads in conjunction with an outer ring at a distance of some 20 km. from the centre.* For several reasons, among which the conflict of local interests is not the least important, progress with the scheme has been slow.

Attempts have also been made from time to time to check the continued concentration of industries, particularly aircraft works, in the Paris region, as this was considered to be strategically dangerous. In 1931 a fund was instituted to assist the removal, if required by the Air Ministry, of aircraft factories to a particular zone, and the scope of this measure was afterwards enlarged. Three years later the Departments of National Defence ruled that works thereafter established in the region should in general be excluded from their supply lists, and in 1938 official approval was required for the siting of new munition factories. It does not appear that this movement had made any considerable progress before the outbreak of war, one obstacle being the disinclination of the workers to migrate with the factories.

BIBLIOGRAPHICAL NOTE

(1) An account of the geographical factors important in the development of Paris will be found in the following articles and books:

See vol. 1, p. 249, of this Handbook. A detailed map showing the density of population in Paris and the Paris region in 1931 can be found in the *Atlas de France*, Plate 72 (Paris, n.d.).

Chapter III

AGRICULTURE

Introduction: Wheat: Other Cereals: Root Crops: Minor Crops: Wine and other Beverages: Market Gardening: Livestock: Working Population: Land Tenure: Legislation: Forests: The Vichy Regime: Bibliographical Note

INTRODUCTION

France is a country highly favoured by nature from the point of view of agricultural production. Of its working population, 35% are engaged in agriculture, and the urban areas are to a great extent fed by home-grown food. A map showing density of population exhibits a remarkable continuity in distribution; only in the highest parts of the Alps and the Cevennes and on the sandy forested stretches of the Landes are there any considerable empty areas. Cultivation penetrates far into the highlands of the Alps, the Vosges and the Jura, following the terraces of the river valleys; it covers the lower platforms of the Central Massif; it renders return, however meagre, even to the dense population of the poor acid soils of Armor in Brittany. If pastoral pursuits and forestry are included, there is hardly a corner of the country left unproductive.

Climate, soil and relief have greatly contributed to this high degree of land utilization, and to these factors must be added the late development of French industry. Both climatic and soil conditions present considerable variety. Exposure to Atlantic winds precludes the harsh winter conditions of more northerly and more continental areas, so that the sheltered bays of the Breton coasts are able to grow early vegetables for export. The extension southwards to Mediterranean shores and the protection afforded by the Cevennes and the Alps against northerly winds give to France a share in Mediterranean products, and have made possible the large-scale cultivation of *pruneurs*; yet, except in the Rhone delta and the eastern-facing valleys of the Pyrenees, the summer drought is not sufficiently prolonged to make cultivation entirely dependent upon irrigation. In the east of the country there is an approximation to continental conditions of agriculture, with the cultivation of maize, hops and tobacco in the lowlands. Finally, the ample development of mountain and plateau in the south and south-east with Atlantic-facing slopes is the basis for pastoral and forest industries.

A generalized view of the soils of France is difficult, partly because of the variety of soil types within a small area, partly because centuries of intensive cultivation, marked even by the transference of soil from one locality to another in barges, has made the present distribution in some areas almost artificial. Despite this, certain predominant soil groups are apparent. The most important contrast is between mountain and lowland soils. The former vary from the rich soils of the volcanic districts of the Central Massif through the moderately fertile calcareous soils of the Jura to complete poverty in parts of the Alps and Pyrenees. Acid soils, too inaccessible for economic liming, must be content to produce such 'poor man's crops' as rye and buckwheat. The lowland soils are equally variable—from the poor sands of the Landes and the sands underlain by clay of the Sologne to the rich alluvial deposits in the river valleys. The prevalence of limestone and chalk ensures large areas of warm, well-drained land; the distribution of *Union* on these high, limestone plains of northern France provides a fairly heavy, loamy soil, suitable for wheat, sugar beet and other root crops. Sunny, south-facing slopes on well-drained limy or gravelly soils produce vines as far north as the river Aisne (Fig. 46). Alluvial river terraces, especially when covered with loessic deposits, are intensively cultivated throughout the land. Ill-drained valley bottoms, moorland, coastal marshes and mountain shoulders or 'alps' provide meadow and permanent pasture.

Upon these diverse soils the intensive cultivation of the small farmer has in many places developed a specialized agriculture, but taking the country as a whole, the yield per hectare is a moderate one for western Europe. It is considerably lower than the yield in such countries of intensive peasant farming as Holland, Belgium and Denmark, and also appreciably lower than the yield in the United Kingdom and Germany, as shown in the following table:

	Yield (quintals per hectare) 1933-7 average			No. of livestock per 100 ha. of cultivated land, permanent meadow and pasture, 1937	
	Wheat	Barley	Oats	Cattle	Pigs
France	15'3	14'3	14'0	45	20
United Kingdom	22'8	20'6	20'4	48	36
Germany	22'2	20'9	19'9	71	83
Belgium	26'5	26'1	26'5	88	52
Holland	29'6	28'7	23'9	109	71
Denmark	31'3	28'4	25'9	93	111

From *Annuaire Statistique*, 1938 (Paris, 1939), which gives *Tableaux Retrospectifs* for a number of countries.

A comparison of the densities of "livestock likewise reflects the different agrarian economies of these countries. Figs. 37 and 38 show the percentages of arable land and grassland respectively in each department in 1938. The proportion of the total agricultural land devoted to each type of farming activity is shown in Fig. 39. The adjoining table summarizes the agricultural production of France.

Summary of Agricultural Statistics, 1938

	Hectares	Quintals (except where otherwise stated)
Cereals:		
Wheat	5,050,199	98,010,002
Oats	3,245,257	54,574,380
Barley	759,223	12,907,804
Buckwheat	261,366	2,422,894
Rye	631,096	8,111,314
Maize	340,290	5,786,067
Millet	9,212	88,266
Other products:		
Potatoes: New	113,235	9,266,727
Others	1,425,000	173,145,000
Sugar beet	319,000	79,800,000
Fodder beet	976,000	382,600,000
Flax	38,000	238,000
Tobacco	18,100	33,166,280 kg.
Hemp	3,802	41,873
Grapes	1,567,000	60,300,000 hl.
Hops	1,600	21,3'00
Cider	—	34,600,000 hl.
Market gardening	437,000	—
Olives	—	333,000
Livestock:	Numbers	
Cattle	15,622,000	
Sheep	9,872,000	
Pigs	7,126,000	
Horses	2,692,000	
Milk	133,241,000 hi.	

The source of this and of other tables in this chapter (except where otherwise stated) was *Statistique Agricole Annuelle* (Paris, latest edition refers to 1938).

WHEAT

In few parts of France are to be found the cool damp conditions that preclude the successful growing of wheat, as in western Britain, and as a result the area under wheat is half that under all cereals. The age-long localization of grain varieties enables most soils that are cultivated with intensive assiduity to be used.

The more important wheatlands (those with an average departmental production of over 2½ million quintals per annum) are situated in the departments to the north and east of Paris (Fig. 40). These areas

Plates 12, 13. Farms in the Bourbonnais

The Bourbonnais lies on the northern edge of the Central Massif between the rivers Cher and Allier. Plate 12 (above) shows the large establishment typical of a former social system; the fifteenth-century *Maison du Maître* lies adjacent to the dwellings of the *metayers* on the left. It is more common for the former to have a separate existence as a chateau. Plate 13 (below) is of a small farm more typical of modern French agriculture.

mainly comprise low limestone plateaux providing a well-drained subsoil covered with fertile surface loams. Wheat is also cultivated intensively on the alluvial terraces of the Seine and its tributaries (Plate 15). Districts with over 15.5 quintals per hectare stretch from the Seine valley to the Belgian frontier. Other areas of high yield are Languedoc, especially on the lava soils, the basins of the middle Rhone, the lower

Fig. 39. Utilization of agricultural land, 1938

Charente region in northern Aquitaine, and the upper valleys of the Mayenne and the Sarthe. Next come the coastal plains of western Brittany, Normandy, the Alsatian terrace lands, and the terraces of the lower valleys of the Alps and Pyrenees. The mountainous regions, together with the coastal regions of the Landes and the Mediterranean, are least important, although even there small areas of relatively level land are utilized (Plate 19).

The area under wheat decreased towards the end of last century as less favourable lands went out of cultivation. Between 1914 and 1918 the decline was rapid due to the ravaging of the north-east by war. Since 1919, the gradual recovery of these areas has been balanced by

Fig. 40. Production of wheat in quintals per 100 ha. of each department, 1938

a steady decline in the south and in other districts such as Normandy, where wheat occupied in 1933 only two-thirds as much land as in 1913. The latter decrease was due in part to the competition of dairy farming. As a result, the total area under wheat has remained relatively constant since 1923 but with a slight tendency towards decline. There has been some restriction in wheat growing as part of a general policy

of avoiding over-production. In 1933, producers were put on an area quota based upon an average of the three preceding years. The yield per hectare, although obviously masked by good or bad harvests, has

Fig. 41. Production of cereals, 1924-38

risen steadily, partly because less favourable lands have gone out of cultivation and partly because of an increased use of fertilizers (chiefly of superphosphates, potash, basic slag, etc.). Thus, although the area under wheat has declined by about 20 % since 1913, the increased yield has resulted in six harvests (those of 1925, 1929, 1932, 1933, 1934 and

Plate 15. Arable farming in Beauce

A photograph taken east of Chateaudun, showing the broad, flat, almost treeless expanse of intensively cultivated land.

Plate 16. Sheep-folding in Beauce

As in Britain, sheep folded on stubble or roots are an essential part of the arable farming economy of limestone regions such as this.

Plate 17. The Champagne Plain

View eastwards from Mt Aime, about 30 km. west of Chalons-sur-Marne. The level or gently undulating plain is between 100 and 150 m. above sea level. Hedgeless cultivated fields alternate with strips and rectangular blocks of planted pines.

Plate 18. Grain elevator near Castelnaudary (Aquitaine)

France is largely self-supporting in grain, and in consequence large quantities are stored at inland towns and not necessarily at the ports, as in Britain. The majority of elevators are owned by co-operative societies, in this case by the *Greniers reunis des agriculteurs Lauraguais*.

Maize yielded 5¾ million quintals in 1938, and it is important only in the south-west where conditions are moist, warm and virtually frost free. It is grown mainly as a fodder crop, and large supplementary quantities have to be imported. Small quantities are cultivated throughout eastern France—a reflexion of the increasing incidence of summer rainfall.

Millet. Only 88,000 quintals were produced in 1938, and of this Vaucluse, a department consisting largely of the Fore-Alpine limestone plateaux, grew almost one-half (41,000 quintals).

ROOT CROPS

Potatoes. Nearly 3 million hectares of ground are under roots and kindred crops, and almost half of that total (i.e. 44%) is occupied by potatoes. They are grown very widely for local consumption, and as the total crop exceeds the requirements for human consumption much of it is fed to pigs or used in the manufacture of alcohol and starch. Two districts specialize in the crop, namely, Brittany, which produces new potatoes, and the area around Strasbourg. Up to 1932, France exported a large amount of early potatoes, especially to Great Britain, but the extension of the Colorado beetle into Brittany has considerably reduced this trade.

Beet. Both fodder beet and sugar beet are grown to a considerable extent in France, roughly in the proportion of four to one respectively. Fodder beet is grown widely in the northern plains, chiefly for the fattening of stall-fed animals. Sugar beet is localized in the extreme north and around Paris (Fig. 43). The beet is grown on large farms in conjunction with wheat, both crops benefiting by the rotation.

Although many sugar refineries were destroyed during the war of 1914-18, the general rise in the standard of living since then has almost doubled the consumption per capita of sugar; the number of refineries is still below the 1914 total, but their output is much greater. The total number of refineries in France is 111, and of these seventy are situated in northern departments. The changes in this area are summarized below:

Refineries in Operation

	1912-13	1920-23	1928	1938
Nord	40	13	13	13
Pas de Calais	24	8	12	12
Somme	33	7	9	14
Oise	20	16	18	18
Aisne	51	11	13	13
Total for five northern departments	168	55	65	70

Fig. 44. Production of wine in hectolitres per 100 ha. of each department, 1938

At the same time as home production increased, sugar imports from the colonies increased almost fourfold compared with pre-1914 totals. As sugar stocks accumulated and the price of beet fell, an agreement was negotiated in 1931 between growers and refineries whereby the price of beet was fixed relatively to the price of sugar, and the refineries accepted voluntary quotas. At the same time the French colonies undertook to limit their shipments to 13 % of the home-produced total. Thus the industry achieved a certain equilibrium without state control, and the area under cultivation has fluctuated but little.

In addition to the utilization of the beet crop for sugar-refining, large quantities are sent to distilleries for the manufacture of alcohol.

MINOR CROPS (Fig. 45)

Flax is grown in the north-eastern departments in the Scarpe and Lys valleys, where a multitude of watercourses makes flax-retting easy. It does not, however, occupy more than 1½ % of the total arable land of the two most important producing departments of Seine-Inferieure and Nord. After a revival which reached a maximum in 1929 (79 % higher than in 1913), economic depression hit the industry, and in 1931 21,000 ha., almost two-thirds, went out of cultivation. The crop has been revived in recent years by a substantial state subsidy and has shown a striking increase since the lowest yield in 1932. In 1938, it was again above the 1913 total.

Tobacco is grown under state regulations and with a subsidy to a small but increasing extent in the south-west (Plate 20), in the two Rhine departments, and to a much less extent in the north-eastern departments and in those of Savoie, Isere and Drome. In Alsace it forms one of the two main crops of the reclaimed Rhine flood-plain—hops being the other.

Hemp is grown to a very small extent by state subsidy in the Loire valley, but in no department does it exceed more than 0.5 % of the arable land

WINE AND OTHER BEVERAGES

Production. France is the most important wine-producing country in the world, although Italy has a greater area under vineyards. But the French yield per hectare (401.) is almost twice that of Italy (22'11. per ha.), and in the production of fine wines France stands alone.

The vine, while not unduly exacting, as it is able to withstand periods of frost, requires a moderate rainfall in spring and early summer with strong continuous sunshine during the late summer and autumn. It grows very widely (Figs. 44, 46) on most types of soil, preferring well-drained stony or gravel soils. The effective northern limit of

Fig. 45. Production of flax, hemp and tobacco, 1924-38

the vine is shown on Fig. 46. The bleak uplands of the Central Massif are obviously not suitable, while the southern Landes and western Pyrenees are subject to warm moist air which encourages mildew. It is interesting to note that the marginal areas of the north, where exceptional and intensive care is necessary, produce some of the best vintages.

Plate 19. Grain harvest in upper Dauphine

Almost every patch of level land in the mountains, snow-covered in winter, is utilized in summer to produce crops of hay, grain or potatoes.

Plate 20. Tobacco cultivation near Beynac (Dordogne)

The rolling limestone country of eastern Aquitaine yields good soils on well-drained slopes. Most of the small farms have a field of tobacco (a carefully cultivated and remunerative crop) and a number of fruit trees.

Plate 21. A Champagne cave at Reims

Storage at even temperature in caves hollowed out of the chalk assists the maturing of the

Vine growing is mainly in the hands of small-scale cultivators, as a vineyard in full bearing fetches a high price per hectare. In 1924, 82 % of the 11 million growers who declared their output had holdings smaller than 2 ha. The remaining large holdings are found chiefly in the Garonne-Dordogne area, where famous Chateau vintages are

Fig. 46. Main wine-producing centres

Based on *Guide Michelin*, p. 28 (Clermont-Ferrand, 1939).

produced, a few in the Loire valley, and a very small number in the Champagne district. Many of the vintage wines such as those of Burgundy are grown by small cultivators and blended by large merchant firms.

Normally over half of the French output comes from the Midi. The grape grown is largely the *petits vins* cultivated on an extensive scale, and it provides the cheap *vin ordinaire* so widely consumed within

the country. The centres of the Midi wine industry are at Beziers, Nîmes, Perpignan and Montpellier (Plate 21).

The second great wine-producing area is in the south-west, and follows closely the valleys of the rivers Garonne, Dordogne and Charente, with Bordeaux as headquarters. About a quarter of the French total comes from here. Four distinct localities produce the high-grade vintage wines. The Medoc region yields fine clarets; south of Bordeaux is the Graves area; on the hills north of the Dordogne lies St Emilion; finally, the much smaller Sauternes district lies on both sides of the Ciron, a tributary of the Garonne. In south-western France are the brandy-distilling areas of Cognac, including the greater part of the departments of Charente and Charente-Inferieure, and the less important Armagnac district in the department of Gers, south of the Garonne.

Another group of wines are the Burgundies, which come from lower Burgundy (the Chablis district), the Maconnais and the Beaujolais; the most important area is the Cote d'Or, between Dijon and Chagny. Here the soil and climate are exceptionally favourable, and owing to scattered villages and the large number of small growers the wines differ widely. About one-twelfth of the French total is produced in this district (Plate 23).

The Champagne area lies in the department of Marne. The four main districts are (1) the slopes of the limestone hills known as the Montagne de Reims; (2) the Cote des Blancs south of the river; (3) the Marne valley itself; (4) and, finally, the lower slopes of the chalk escarpment in the extreme east of the department. The wine, which is essentially an artificial product blended from the output of all of these districts, is the result of careful culture, pressing, fermenting, maturing and blending. The production, however, is inconstant and constitutes a very small proportion of the French total, averaging only about a quarter of a million hectolitres (Plate 21), although in a 'good vintage' year the value is considerable.

Another important wine-producing district is in the Loire valley. The chief areas are in Anjou and Touraine, which yield such famous wines as Vouvray and Saumur; the coastal departments produce white wines such as Muscadet, and the rest of the valley produces large quantities of *vin ordinaire*. The production averages about 5 million hl., about one-twelfth of the French total.

Alsace-Lorraine is also a small producer of wine. The vines are grown on the lower slopes of the Vosges and in the eastern valleys, sheltered from winds and with sufficient sunshine (Plate 24). Much

of the wine is of ordinary quality, but such white wines as Muscatel, Riesling and Turckheim are exported.

Finally, in the Jura a number of notable wines, such as Ch&teau-Chalon and Arbois, together with much *vin ordinaire*, are produced.

Output. The area under vines grew steadily to a maximum of 2,447,000 ha. in 1874; the production of wine for market reached a total of 83.8 million hl. in the following year, a figure which has never again been reached (Fig. 47). Only about 3 % of this total was exported, but in value it was a much greater proportion of the whole. By 1879, production had sunk to 25.8 million hl.; this startling decline was due to the ravages of the *Phylloxera*, an insect native to the United States which had been introduced into Europe between 1858 and 1863 with American vine stocks. The insect multiplied at an enormous rate and attacked the roots of the highly susceptible European stocks, thus tapping the flow of sap and destroying the

Fig. 47. Production of wine and cider, 1830-1938

vine. Over a million hectares of vineyards were destroyed in France, and the financial loss is estimated to have been much greater than the indemnity paid to Germany after the Franco-Prussian War. The pest was overcome by (1) the large-scale introduction of a relatively immune American stock upon which the French vine was grafted, (2) the injection of carbon bisulphide into the ground, and (3) winter flooding where practicable. But the quality of subsequent vintages suffered, and in many localities vine growing was permanently abandoned. By 1911, an area of some 1½ million ha. was under the vine, producing about 45 million hl., and this area has remained relatively stable.

But although the *Phylloxera* was conquered, the wine industry never went back to its previous prosperity. During the years of low production, Spanish, Italian and North African wines made considerable headway. Algeria, being within the French customs territory, rapidly increased its output and sale in France. In addition, the cultivation of the vine in other parts of the world, notably in

South Africa, Australia and South America, caused further decline in French wine exports. South American wines hit especially the export of *vin ordinaire* from Bordeaux to the Latin republics.

The diversion of labour from agriculture during 1914-18 left* the vineyards open to disease, and in 1915 two-thirds of the crop was lost owing to mildew. Since that time the industry has recovered somewhat, but it has been hit by the heavy and increasing English excise duties, by Prohibition in the U.S. between 1920 and 1933, after that by the relatively small import quota allowed by the U.S., and by the general world economic crisis, wherein wine as a luxury product suffered severely.

As wine is the principal drink of the country, it is likely that the total amount produced is very many times that exported. But the home consumption has fallen greatly, owing to the general economic crisis, to unduly high prices, and to the greater adoption of other beverages such as beer and cider. Between 1931 and 1933, many of the great proprietors became bankrupt and their estates were broken up for sale. Since 1933, however, there has been some degree of recovery.

Beer and *cider* are the principal beverages in the areas where the vine cannot be successfully grown, although the first is increasing as a drink generally. *Beer* is produced chiefly in the north and east, *cider* in the north-west. Hops are grown in Alsace and Burgundy, but from the latter area they are sent to the breweries in the Nord and Rhine departments. Both the area under cultivation and the total yield fluctuate considerably. *Cider* is the normal beverage of Brittany and Normandy, and is produced in the apple-growing departments that border the English Channel. The chief feature about the yield is its variability (Fig. 47). Thus the yield in 1938 (34.6 million hi.) was more than twice that of 1937.

MARKET GARDENING

In many parts of France climate and soil, together with intensive skilled labour, have resulted in the localization of special crops. Adjacent markets in large towns have encouraged the large-scale production of 'perishable' commodities which command a good price. With the organized development of fast main-line trains with refrigerator cars (notably by the P.L.M.) and of motor transport, district surpluses have been sent farther afield. Thus Vaucluse and Var are able to send fresh produce to Paris, while a large amount of table fruit,

Plate 22. A vineyard near Narbonne (Aude)

Extensive vineyards in the Midi yield vast quantities of *petits vins*, grown and processed for the production of cheap *vin ordinaire*.

Plate 23. A Burgundy vineyard

The typical unit of production in the wine industry of Burgundy is the *dos*, of relative y small extent, from which the vintage derives its name—in this case Clos-Vougeot. Behind the chateau is the escarpment of the Cote d'Or.

Plate 24. Vineyards at Ribeauville (Alsace)
Alsatian vines are grown on the lower south-facing slopes of the Vosges.

cut flowers and other luxury produce from Provence appears in the London markets. As a result, in 1938, 143,042 people were engaged exclusively in the cultivation of fruit and 39,084 people in the cultivation of flowers. Of the total area devoted to horticulture in 1938 (that is, about 437,000 ha.) 304,000 ha. were cultivated for subsistence and the remainder for the production of cash crops for market—vegetables, fruit, flowers and shrubs (Plate 25).

Vegetables. In mild damp regions, such as the sheltered bays of Brittany and the Marais Poitevin, early products (*primeurs*), notably cauliflowers, new potatoes, onions and tomatoes, are cultivated for markets in Paris, England and the industrial north-east of France. The lower Rhone valley offers similar possibilities over a longer period of the year, and in Provence and Roussillon all types of early vegetables for salads are grown. In many districts, vineyards have been uprooted to make room for the more lucrative production of *primeurs*. Here irrigation, protection from the mistral by cypress and wattle fences, and smoke screens against frost are necessary (Plate 26). Around the large towns, market gardening and glass cultivation produce vegetables for the urban markets. In certain districts, notably round Bordeaux and Metz, peas, beans, asparagus, etc. are grown for canning and bottling.

Fruit. In a climate which has much sunshine fruit growing will clearly be important. The commercial production of fruit is carried on in many areas, and once again localized specialization is the case. Notable features are fruits for canning and crystallizing in Gascony, high-class dessert fruit of all kinds in the Rhone valley, cherries for bottling and sugaring in the upper Rhone area, black currants for making *cassis* round Dijon, almonds, figs and citrus fruits on the Mediterranean coast, walnuts in Isere, chestnuts on the Central Massif and the olive on the south-facing terraces of the Midi. The last is near the northern climatic limit and frosts may be destructive, but some oil is produced for margarine and soap as well as for export in a refined state. As in most Mediterranean lands, much olive oil is used locally for a wide variety of domestic purposes in place of animal fats.

Flowers are cultivated on the Cote d'Azur for making perfume and for the 'cut-flower' export trade; the centre is Grasse (Plate 27). Another example of large-scale specialization is the production of roses in Brie and Provins.

Silk. The cultivation of the mulberry may be linked with market gardening. It is cultivated on the lower slopes of the middle Rhone valley and of the Mediterranean coast, but the production of home raw

silk has decreased greatly. The cottage industry of silkworm rearing was halved between 1913 and 1936, largely due to competition by imported raw silk from Piedmont, Syria and the Far East. Production of silk is carried on in seventeen departments, the most important being Gard, Drome, Ardeche, Var and Lozere (see pp. 239-40).

LIVESTOCK

There are three types of natural pasture in France, namely, the upland type, the lowland *bocage* type, and the smaller areas of coastal saltmarsh.

The summer upland pasture is very varied. It includes the *alpages* or *alps* between the permanent snow-line and the tree-line (Plate 28). Animals are taken there from the valleys in early summer to graze until autumn. Other varieties of upland pasture include on the one hand the scanty herbage of the limestone Causses and the heath pastures of crystalline uplands, and on the other the better pasture of the well-watered lower plateaux such as Limousin, and of the rich volcanic soils of parts of the Central Massif.

The lowland *bocage* type is found where the rainfall is evenly distributed throughout the year and where conditions are mild, as for example in Normandy, Brittany and Vendue. The rank grass is suitable for cattle grazing. In general, too, hay meadows are conspicuous features in the broad clay vales that separate the higher limestone plains in northern France.

The third type is saltmarsh pasture found notably in the Crau and Camargue districts of the Rhone delta, and along the Vendee and Breton coasts.

The distribution of permanent pasture is shown on Fig. 38. The rearing of stock is, of course, not confined to these natural pastures, but is carried on in many places in conjunction with arable farming (Plate 16).

The number of cattle has risen slowly from 1875 to 1938, with but little break during 1914-18, and has stabilized at about 15 ½ millions. Sheep, however, decreased sharply during that period to just under 10 millions and are still significantly below 1913 figures; and pigs also declined, although they recovered their pre-1914 numbers in the next twenty years. The large war-time losses of horses had been almost made good by 1929.

Cattle are reared in most parts of France (Fig. 48), the least important area being along the Mediterranean coast, although even

Fig. 48. Distribution of cattle per 100 ha. of each department, 1938

Fig. 49. Distribution of sheep per 100 ha. of each department, 1938

there the Camargue is rather an exception. One important cattle area is the Armorican peninsula, despite the high proportion of ploughland and the low proportion of natural pasture. The Cotentin department of Manche has a greater density of cattle than any other in France; its cattle average 91 per sq. km. compared with the general French average of 29; the corresponding figures for milch cows are 51 and 17 respectively.

On the Central Massif, cattle are reared in the departments of Cantal and Haute-Loire, and in the more northerly departments of Allier and Saone-et-Loire (the natural pastures of Charolais (Plate 32)). An outstanding breed is the Salers. The animals are grazed in summer on the pasture of the volcanic soils of the plateau and are hay fed in the valleys in winter. Other important districts are in Picardy and Artois, in the Vosges, in Savoy, where the Tarentaise breed are kept, and in the Pyrenean foot-hills. Transhumance, that is the seasonal movement of animals to the high pastures in summer, is practised in nearly all upland areas.

Dairying is most important in Normandy, the Charente, Jura and Savoy. On the whole, production is backward and milk yield low, due to the multiplicity of breeds which hinder the organization of breeding societies, to the lack of a farming aristocracy interested in scientific breeding, to insufficient supplementary feeding of roots and oil-cake, to the prevalence of disease such as tuberculosis, to bad housing, and to lack of co-operation. Only in the Charente, and to a less extent in Normandy, Savoy and Jura, is there much co-operative organization. Although far below Danish or Dutch standards, Charente butter fetches the highest price on the Paris market.

Co-operation in the Charente

	No. of societies	No. of members	No. of cows	Milk handled, million litres	Butter produced, tons
1883	1	90	330	0'6	31
1908	112	67,026	165,021	246	11,636
1928	134	87,694	263,303	446	19,647
1938	134	77,820	271,539	447	19,775

From P. L. Yates, *Food Production in Western Europe*, p. 267 (London, 1940).

Other parts of France have a number of small-scale co-operative dairies but primitive independence is more usual. By far the greater **part of** butter and cheese is made on the farms or in the dairy chalets in the mountains. Such varieties as Gruyere in Savoy and Jura,

Plate 25. Market gardening at Chatillon (near Paris)

In the Paris suburbs, as around many great cities, vegetables are intensively cultivated.

Plate 26. Cultivation of *primeurs* at Chateau-Reynard (near Avignon)

Early vegetables are protected against the mistral by tall hedges of osiers.

Plate 27. Flower cultivation near Grasse (Alpes-Maritimes)

The south-facing slopes below the ramparts of the hill-top village of St Paul are divided by wattle fences into sheltered plots, where flowers and aromatic shrubs are grown for the perfume industry.

Fourme and Laguiole in the Central Massif, and Gerojne-Munster in Lorraine are almost entirely farm-made. In the north there is an increasing output of factory cheese, although much is still farm-produced by individuals; named varieties include Brie, Camembert, Pont l'Eveque, Livarot and Maroilles (Fig. 50). The increase in production which rapidly overtook consumption after 1918 inevitably

Fig. 50. Main cheese-producing districts

Based on the *Atlas de France*, Plate 40 (Paris, 1934),

led to a decrease in prices, accentuated very markedly by the rapid increase in imports. As a result, quota regulations were imposed to restrict imports of butter, cheese and margarine, and a subsidy in 1935 helped to finance the butter export trade. The milk industry is almost wholly unorganized owing to small-scale production, and only in Paris is there any large marketing organization.

Meat. The production of meat is secondary to milk but is not unimportant. The increase in numbers of animals in post-war years has

resulted in a supply sufficient to meet the home demand; some animals were even exported to Italy.

A large proportion of the meat is veal, which is very widely produced because many cows are calved for the sake of their milk; the calves are slaughtered young to save the cost of feeding. There is a certain amount of specialized bullock fattening, especially in the north, where store cattle brought from the Cotentin, the Charolais and Limousin are fattened indoors on sugar-beet pulp and oil-cake. The chief market for fat stock is at La Villette in Paris. Provincial slaughterhouses on a larger scale have been tried, but have failed owing to the small-scale production and the seasonal fattening system which results in long periods of inactivity. The rearing and training of bullocks for draught purposes (Plates 34, 35) and for the plough goes on in most places, but it is a special occupation in the farms of the Central Massif.

Sheep are reared mainly in the departments around and to the north of Paris, in the Central Massif where Aveyron and Lozere are the chief departments, in the Rhone delta and along the Pyrenean foot-hills (Fig. 49). They are also reared on the rougher pastures of the Cotentin, on the saltmarshes of the coast of Brittany and Normandy, and on the drained marshes of Deux-Sevres, Charente and Charente-Inferieure. In the Crau and Camargue districts of the Rhone delta extensive grazing is practised, and flocks are sent to the Alpine districts of Dauphine and Savoy, often by rail, for the summer months (Plate 30). In most of these districts sheep are kept both for wool and mutton. In the Causses, milk of sheep is used for cheese making, and there are over 500 concerns making the well-known Roquefort cheese (Plate 33).

The total number of sheep in France has declined drastically, and in 1938 there were only half as many as in 1900. Among causes to which this decline is attributable are the increase in wages and consequent difficulty of finding shepherds, the disappearance of biennial fallow in the southern part of the country, and low wool prices. As a result there is a large import of sheep, chiefly from Algeria, and of wool.

Pigs. Production is almost entirely unorganized and is devoted to supplying local markets. One or two areas, including Brittany, the Limousin district, Lorraine and Artois, have a certain degree of specialization for ham production, especially where they utilize skimmed milk and whey from the dairies. Apart from those, pigs are kept on a small scale as a secondary source of food almost everywhere but especially by poorer peasants. They are fattened for slaughter in

Fig. 51. Distribution of pigs per 100 ha. of each department, 1938

Fig. 52. Distribution of horses per 1000 ha. of each department, 1938

late autumn and constitute the winter meat supply. Although the quantity sold to the public has increased, over 40% is still consumed on farms. War-time slaughtering between 1914 and 1918 caused a rapid decrease, but since then numbers have increased steadily and the 1938 total slightly exceeded that of 1913 (Fig. 51).

Horses, etc. Despite the extensive development of mechanical traction and the virtual disappearance of horse-drawn vehicles in towns, the horse has held its own since 1918 after the heavy war-time losses. The total number in 1938 was 83·6% of that in 1913. The chief horse-rearing areas are in Brittany, where Finistère has more head (20) per square kilometre than any other department; then come Mayenne and the north-eastern departments (Fig. 52). The animals are bred largely for ploughing.

Mules and asses are used extensively as beasts of burden, there being 135,000 and 85,000 of them respectively in 1938. Mules are used in the south-east and south-west of the country; numbers of donkeys are to be found in Manche and Calvados in the north and in the northern part of the Central Massif, especially in Corrèze.

Other Livestock. Goats and *basse-cour* animals, that is poultry and rabbits, are kept largely as supplements by the small farmers, yet the total value is estimated to be about two-thirds that of the entire wheat crop. One or two goats are often kept to provide milk for those who cannot afford a cow, or maybe a few goats are pastured with the cattle. In some areas to the south of the Loire and in the Rhone valley the goats-milk is made into well-known local cheeses. A number of large farms near Paris produce eggs commercially, but the remainder of the home market is supplied by a very fluctuating yield from the general farms; only about 10% of the eggs that appear in the market are imported.

WORKING POPULATION

In 1931, nearly 7 million people were engaged in agriculture and allied pursuits (Fig. 53), representing approximately 35 % of the working population (Fig. 55); of these just over 3 million were male. The total represents a decrease of over 1·6 million on the 1911 figures, as shown by the following table:

Millions of workers engaged in agriculture

	Male	Female	Total I
1896	5·7	2·8	8·5
1911	5·3	3·2	8·5
1931	3·1	3·8	6·9

(Excluding Alsace and Lorraine)

From P. L. Yates, *Food Production in Western Europe*, p. 283 (London, 1940).

Fig. 53. Distribution of agricultural population per 100 ha. of each department, 1931

Fig. 54. Changes in rural population, 1881-1931, by departments

Statistics from which these figures and also Figs. 55, 56 were drawn were taken from vol. 1, part 3 of the *Recensement general*, 1931 (Paris, 1935).

The large decrease in male agricultural workers is striking; the less marked although considerable total decline is partially compensated by the persistent increase in female labour. This decline has not been uniform over the whole of France. Between 1881 and 1931 the numbers of rural dwellers actually increased in three departments (Fig. 54), but in no case by as much as 5 %. During the same period the most marked decrease was in the departments of Seine, Seine-et-Oise and Alpes-Maritimes where the agricultural population was halved, and in the departments of Rhone, Pas-de-Calais, Meurthe-et-Moselle and Belfort where the decrease was between 40 and 50%. In thirty-six departments the decrease was less than 10 %, notably in Brittany, the Loire valley and the Central Massif. The rural exodus is of long standing; it has been a feature of the mountainous parts since the middle of the last century, but it became more general after 1881. This was due to a variety of causes, including the abandonment to stock of poorer lands, the increase of machinery, the decay of rural industries, the drift to the more attractive work and wages-of the towns, and a birth-rate even lower in rural areas than the generally declining French rate, the result maybe of efforts to reduce the effects of divided inheritance. Yet agriculture is still by far the largest occupational group, and since 1930 the number thus engaged has started to rise again as a result of industrial unemployment. In 1931, 60% of all those employed in agriculture were their own masters either as owners, tenants or *metayers* (see p. 131), while the remaining 40% were labourers or employees in some capacity. Of the latter, 71 % were male and 29 % were female, either workers on the land or farm servants. In 1932, an inquiry into the question of agricultural wages yielded the following results:

Average daily earnings in francs

	1924	1928	1930	1932
All labourers	14-80	20'60	2250	2235
Male labourers		18'94	20'85	20'75
Wagoners		21'56	23'73	23'00
Female labourers		14'20	15'41	15'38
Female servants		13'58	14'74	14'72

The trend of these wages, namely, a steady rise to 1930, then a slight fall, has followed very exactly the trend of wages of other occupational groups. The above figures are averages for the whole country but differ widely in different districts. The proximity of large cities, industrial areas or coalfields necessarily forces agricultural

Over 39%	20 - 29%
34 - 39%	9 - 20 %
29 - 34%	Under 9%

Fig. 56. Systems of land tenure, 1932, by departments

wages up to meet the industrial competition for available labour. Thus around Paris the average wage per annum in 1937-38 was 14,050 fr., but in Ariege and Hautes-Alpes the figure was only about 4,000 fr. Average pre-1939 French agricultural wages (about 20s. to 25s. per week) compare favourably with Belgium (18s. to 22s.), but very unfavourably with Great Britain (33s. to 40s.).

Most people engaged in agriculture live permanently on the farms where they work, but there is some seasonal movement. This consists partly of a small shifting semi-urban, semi-rural population and partly of a seasonal influx of foreign labourers, but in no case is it great in amount, as the harvest on the characteristic small-holding merely involves the intensive and lengthy labour of all members of the family. The census of 1929 gave a total of over 800,000 men and women of French nationality employed temporarily in agriculture, that is, one-eighth of the total agrarian workers.

In 1929, there were a quarter of a million foreign agricultural workers in France, of whom half were permanently employed. Spaniards, Belgians and Italians from the adjoining countries formed the bulk of this labour, but Poles, chiefly because of their low standard of living and willingness to work for a very small wage, were also numerous. The Poles work mainly in the sugar-beet areas of the north-east, while the Spaniards and Italians are found along the Mediterranean littoral. Full details of the foreign elements in France are contained in Appendix I, pp. 375-92.

LAND TENURE

Farmland in France is cultivated by an owner-occupier, or by a tenant-farmer, or by a *metayer* or 'share-tenant' (Fig. 56). The proportions of these in 1929 were as follows:

	% of holdings	% of area
Owner-occupiers	75	60
Tenants	20	30
<i>Metayers</i>	5	10

From P. L. Yates, *Food Production in Western Europe*, p. 277 (London, 1940).

The owner-occupiers are in the great majority in the south and east, where many departments have 90% of their cultivable land farmed by the owners.

Less than one-third of the total agricultural area of France is cultivated by tenants, although in five departments of the Seine valley more than 70 % is cultivated in this way. In this area farmers and landlords

Plates 28, 29. The hay harvest

In mountain areas the hay crop is a vital part of the farming economy. Plate 28 (above) shows the method of stacking in the Alpine district, where high winds and heavy rain are frequent; Plate 29 shows a mountain farm in the High Vosges of Alsace.

Plate 30. Mountain pasture in Haute-Savoie

Plate 31. Cattle grazing in Brittany

These two plates show the contrast between scanty mountain pastures, where sheep roam over wide areas, and rich cultivated *pratnes artificielles*, where restricted grazing by tethered **cattle is part** of a mainly arable farming economy.

co-operate to maintain the farms in the best possible condition. In other parts of France, such as the Sologne, farming is spoilt by sport, and the farmers, who are entitled by law to receive compensation for damage, often live on the compensation.

Metayage, or share-tenancy, is a system whereby the landlord provides the farm, implements and livestock and in return takes half the produce as rent. The landlord may be a landed proprietor, an absentee capitalist, or sometimes a small farmer who has invested in a second holding. There has been a considerable decline in the system in the last hundred years, and only in the departments of Landes and Allier is over half the agricultural area cultivated on this system. Its disadvantages are obvious, for it encourages wasteful cultivation; the tenant is tempted to put in as little and to take out as much as he can; insecurity never makes for good farming. A hard-working single man can earn more as a hired labourer and therefore save enough to buy his own holding in due course. The *metayer* is usually a man who has no capital but can utilize the labour of a large family.

France is a country of smallholders; in 1931, 85.1% of the total number of holdings were less than 10 ha. in area. On the other hand, the remaining 14.9% of the holdings occupy nearly three-quarters of the total area of France (excluding forests).

Size of holding (in hectares)	Number of holdings	% of total	Area of group (hectares)	% of area of France (less forests)
0-1	2,235,405	39.2	1,327,300	2.6
1-10	2,617,558	45.9	11,244,700	22.8
10-50	764,461	13.5		
50-100	52,048	0.9	36,806,800	74.6
Over 100	33,280	0.5		
Total	5,702,752	100	49,378,800	100

The larger holdings are almost entirely in the north-east (Fig. 57) and are devoted to growing sugar beet. Around Soissons, for example, the farms are from 300 to 400 ha. The number of large holdings has decreased during the last 40 years. Some of them were broken up in 1918 in default of heirs, or because of shortage of labour or lack of capital. Holdings of under 2.5 ha. are mainly in the vine areas. The most typical is that of 10-25 ha. with a mixture of horticulture, agriculture and livestock, and this type occupies nearly half the total cultivated area. The smaller grower is favoured by the Wheat Growers'

tax which was imposed in 1938 and which is on a sliding scale, rising sharply with an increase in the area of the holding.

The problem of the prevention of the continual splitting up of the holdings due to the laws of inheritance has given rise to many difficulties. While the principle of the equal division of property among the children had been practised in some districts before 1789,

Fig. 57. Average size of holdings in hectares, 1930, by departments

Napoleon's Civil Code enforced this. Although some children might be bought out, subdivision inevitably increased. In the department of Meuse, for example, one farm of some 30 ha. was divided into about 2,000 'parcels', with each peasant owning twenty or thirty scattered about the whole holding. There have been various attempts, none of them very successful, to meet this problem (pp. 133-4).

LEGISLATION

France is divided for the purposes of agricultural administration into eight regional offices responsible to the Minister of Agriculture. A regional office in turn has the general supervision of the departmental offices within its area. A departmental office is directed by five representatives of the agricultural interests of the department and is managed by trained agriculturalists.

General Policy. The state's agricultural policy has consisted of a spasmodic series of relatively unrelated schemes. Direct subsidies have furthered large schemes such as rural electrification, water supply, road and rail improvements, and the use of fertilizers. There has been a gradual improvement in agricultural inspection, in the registration and compilation of production returns, and in the establishment of agricultural schools, research stations and breeding establishments.

Finance. Almost one-half of the agricultural population are borrowers who obtain credits from the National Mortgage Bank (*credit fonder*) or from the numerous agricultural credit banks, through which direct state loans are made. Other sources are the solicitors and merchants connected with agriculture, and the Joint Stock Banks, together with private organizations such as Peasants' Unions, the Durand Banks and the co-operative banks of Alsace and Lorraine.

Labour. Some effort has been made to improve the lot of the rural worker. Between July 1929 and November 1932 a series of regulations dealing with the accommodation of labourers were passed, and in March 1932 the extension of compulsory family allowances to include agricultural workers was effected. In December 1932, the law enforcing the submission of disputes between employer and employee to a conciliation board (*consdl des prud'hommes*) was applied to agriculture. It had already been operating for industrial disputes. To strengthen the employer's position, a law was passed in February 1932 whereby a former employer might secure damages from the new employer in the event of a labourer breaking a contract to change his job. This helped to check the evil of enticement.

The Size of Holdings. Efforts have also been made to meet the problems of division of property by inheritance. In 1908, a law was enacted which allowed a holding not exceeding the equivalent of £320 to be registered as inalienable. But this figure was much too low and subdivision had already gone too far when it was reached. Regrouping with all its saving of time and efficiency could only really be accomplished by energetic individuals through sale, marriage or

exchange. Clearly, a single person could spoil any scheme by withholding his consent. A state-sponsored regrouping scheme in 1919 helped but little, as a majority vote of a commune was still necessary before the state could take the necessary steps. When a commune agreed to a regrouping scheme, the government paid 80 % of the cost of regrouping as a direct subsidy. As a result, about 600,000 ha., chiefly in the north-east, were regrouped between 1919 and 1929. In 1935, a further act was passed to simplify the procedure for regrouping, but as the initiative is still largely left to the peasants little has been done.

Protection. The state has also pursued a strong policy of protection and encouragement of home agriculture by imposing tariffs and import quotas on a wide variety of agricultural produce, including specified items from particular countries. The problems of over-production at home have been partially tackled by restrictive area quotas and by marketing regulations. The measures adopted towards the two most important commodities, wheat and wine, illustrate the nature of the difficulties and the efforts to overcome them.

In the case of wheat, the outstanding problems in recent years have been those of over-production and of marketing. During 1931 and 1932, imports were still much above average (Fig. 42) in spite of the tariff, while subsequently there were good crops in the years 1932, 1933 and 1938. Efforts were made to limit surpluses by putting growers on an area quota; a 'Wheat Commission' was instituted to dispose of surplus supplies and a minimum selling price was fixed, although in practice it could not be enforced. In 1935, the establishment of new flour mills was forbidden. In 1936, a 'Wheat Office' with local branches was set up to deal with problems of over-production and marketing. Growers were compelled to state the area they had sown and the quantity of wheat harvested; apart from their own consumption, they had to sell to the local co-operative society (Plate 18) or to a licensed dealer. In 1938, the harvest was good and a surplus was the result. To deal with this a tax on producers was imposed.

The great over-production of wine, the obstacles to its export and increasing imports have led to several legislative attempts to meet the situation. In July 1931, it was enacted that no individual or undertaking in France or Algeria owning 10 ha. or harvesting 500 hi. should plant any more vines for 10 years, and fines were imposed on excessively high amounts. The first of these measures was abrogated in the same year as its imposition, but it was re-enacted in July 1933, when for a period of 5 years no increase of vineyard area was to be

Plate 32. Grazing on the Charolais plateau

Rich pastures on Jurassic limestones are utilized to fatten the famous white Charolais beef cattle.

Plate 33. A cheese cave at Roquefort (Aveyron)

Cheeses, made from sheep's milk, are matured in caves hollowed out of the limestone cliff, on the slopes of which the town of Roquefort is situated.

Plates 34, 35. Ox transport in southern France

Oxen are used extensively as draught animals in many parts of France, notably in Aquitaine. Plate 34 (above) is a scene in St Jean-de-Luz. Plate 35 (below) shows the collection of seaweed on the coast at Hendaye; it is spread on the nearby fields as a fertilizer.

allowed. In July 1932, a system of 'blocage' was put into operation whereby the government was empowered in the event of over-production to fix the amount of wine to be put on the market. In that month no grower harvesting 500 hi. could sell a quantity of wine exceeding two-thirds of his total harvest. Each producer of wine had to register and obtain permits for the sale of produce, while the local Marketing Committee had to release the output as the market could absorb it and thus maintain a minimum price. The whole system hits the larger producers who have to release part of their crop to distilleries at low prices, while the small producers are able to sell at much better prices in the open market. In 1934, cultivators were paid the equivalent of up to £40 per acre for the destruction of their vineyards, but they were not to replant or to grow certain other specified crops, notably tobacco, flax and sugar beet.

Owing to the fact that the majority of growers have holdings less than 1 ha. and are therefore largely untouched by legislation, the schemes to restrict vineyards are ineffective; there was more land under vines in 1938 than at any time since 1913.

French growers have long agitated for a restrictive quota on imported Algerian wine, as the lower costs of production and the large export from the non-wine-drinking Mohammedan population, together with freedom from foreign import duties, affects adversely the home industry. But up to 1936 no legislation had been effected.

FORESTS

Of the total surface area of France about 10½ million ha., that is 19·4%, are forested (Figs. 58, 59). Similar figures for Great Britain are 1¼ million ha. and 5·4% respectively. The woodland is scattered over the whole country, with concentrations partly in certain parts less suitable for cultivation, notably on the bleak exposed uplands and on coarse sandy soils, and partly in preserved state-owned areas. Sixteen departments in 1938 had over 30% of their total area under wood (Fig. 58). In some districts, however, chiefly in the north-west and north-east, forests which once existed on well-drained lowlands have been removed by centuries of intensive cultivation, and woodland now exists only as coppice.

Of the French total of 10½ million ha., 14·4% is state forest, comprising chiefly the afforested areas, and are well maintained by the department of *Eaux et Forêts*, which administers them under a code of forest law.

Another 20-9 % belonging to communes and public bodies are also administered by the same department, while the remainder (647%) is in the hands of private individuals. The proportions of coppice, deciduous and coniferous woods may be seen from the following table:

Forests of France, 1929. Thousands of hectares

Coppice	Deciduous	Coniferous	Total	Recently planted	Total
6,480	1,122	2,777	3,899	292	10,671

Fig. 58. Percentage of area covered with woodland in each department, 1938

The forests may be divided into three main groups, namely, the Mediterranean type in the south-east, the cooler temperate forest of the Atlantic seaboard and hinterland, and the upland forests. Although there is a considerable diversity, areas of certain dominant species may be broadly distinguished.

The major areas of natural woodland will first be considered, then the regions where extensive afforestation has taken place.

*Natural Woodland**(1) The Mediterranean Forests*

These may be divided into two groups, those in Provence and in Languedoc. In the former area, the Aleppo and maritime pines are indigenous, and occur in uniform stands. There are also many exotics and tropical plants in the parks and gardens of the Riviera coast. In

Fig. 59. Distribution of woodland, 1932

Based on the *Atlas de France*, Plate 38 (Paris, 1935).

Languedoc both coniferous and deciduous trees are represented; they include various species of pine, several varieties of evergreen oak and edible chestnut. Other deciduous trees scattered more generally are the lute-tree, some varieties of ash, poplars along the banks of the Rhone, planes, Montpellier maples and alders.

These southern woodlands have been extensively ravaged in this area by cultivation, by past exploitation for shipbuilding, by over-

grazing and by several disastrous fires. In many places a secondary growth has established itself—*garrigue* on limestone and *tnaquis* on siliceous soils. The words themselves are sometimes used to denote the type of country as well as the type of vegetation. *Garrigue* is found mainly to the west of the Rhone in Gard and Herault, on limestone plateaux averaging 150-300 m. but reaching 800 m. in places; they are also found behind Toulon. In *garrigue* the dominant plant is the stunted kerm oak, which grows in thickets, but many other plants thrive—grass, thyme, and more often shrubs like lavender, juniper and cistus (rock-rose). Areas of rock and stony soils bear the arbutus (strawberry tree), laurel and mastic trees, and the asphodel. The majority of these plants are remarkable for their strong scent. Thus *garrigue* country has a rich variety of plants, and belies a first impression of desolation and poverty. All *garrigue* plants possess drought-resisting features such as thorny structures, or leathery, shiny or curled leaves, or long ropts. The drought which limits the growth and type of vegetation results from several factors: a thin soil covering, the permeability of limestone rock, the rapid run-off of rainfall, and the high temperatures and excessive evaporation which prevail during summer when rainfall is lowest.

The *tnaquis* is less varied than the *garrigue*. The country east of the Rhone has more frequent silicious rocks (sands and marls), and here the maritime pine is dominant. These pine forests permit the development of a very dense shrub vegetation of cistus, arbutus and broom. Growing in a less permeable soil, the plants have not such pronounced drought-resisting features as *garrigue* vegetation. The dry nature of the vegetation as a whole and the resin secreted by the pines make the *maquis* particularly liable to the danger of fire.

These two vegetation groups have a complicated history. In Languedoc the *garrigue* is the work of man; the original natural vegetation included many woods of ilex or holm oak, protecting the thin soil which nourished them. Destruction of these valuable trees permitted soil erosion, and on the resulting stony uplands they were followed by thickets of stunted kerm oak. In places where many successive fires have occurred the *garrigue* is replaced by grass steppe, and with overgrazing even this fails to replace itself, and gives way to the final triumph of the asphodel. If, on the contrary, the grass cover is not grazed by animals, it is invaded by thickets of kerm oak, which eventually allow the return of the ilex oak, first in copses, then in forests (though a forest is rarely given time to recover in this way).

The kerm oak was formerly more widespread, and in the eighteenth

century many oaks still survived in the inland parts of the Maures. The progressive removal of these more valuable trees allowed the pine, a latecomer, to take root. The oak has been able to colonize successfully only the limestone country which is unsuited to pines. In the Maures and Esterel massifs, east of the Rhone, abandoned agricultural clearings are invaded first by kerm oaks, but these are in turn stifled by the pines coming back to reconstitute the maquis. Once the maritime pine has secured a foothold it rarely retreats; in spite of fire it replaces itself without human intervention, and the dense closed vegetation of the maquis which follows is able to stifle any oak seeking to re-establish itself in its former territory.

(2) *Temperate Forests*

The undulating plains and hills of the Atlantic seaboard and its hinterland are covered with deciduous trees except where coniferous afforestation has taken place. These temperate forests cover three-quarters of the total area of France and may be conveniently divided into two regional groups, namely:

(a) *Aquitaine and the south-western plain.*

(b) *The north Atlantic coast, the Paris Basin and north-eastern France.*

(a) *Aquitaine and the south-western Plain.* This area is climatically a transition zone between the maritime temperate and Mediterranean regimes, and as a result the vegetation exhibits transitional characteristics. Several species of the southern deciduous trees are found, including the cork oak on the siliceous soils south of the Garonne, the Montpellier maple as far north as Poitiers and Niort, the ilex oak and the pubescent oak in the south, and the pedunculate oak in the lower valleys. Elms and beech occur notably in the forests of Chize and Aulnaye. Conifers, apart from the great afforested Landes (see pp. 141-2), are represented by scattered patches of pines on the hills.

The natural forests on the whole are not extensive, as much of the region is under vineyards, market gardening or permanent grazing.

(b) *The North Atlantic Coast, etc.* The dominant species of this extensive zone are the pedunculate and English oaks, although most of the temperate deciduous trees are represented. Beech trees are common everywhere except in the Loire valley. The fine old domanial forests are largely made up of the two oaks. The mild winters allow the persistence to an unusually northerly latitude of some of the southern evergreen trees. Many conifers have been naturalized, especially on sandy areas such as the Sologne (see p. 142), but

only in rarer places on the uplands, notably in Alsace, are they indigenous.

Some of the largest individual forests other than the afforested areas occur in this region. They include the Forests of Orleans (34,344 ha.) and Fontainebleau (16,855 ha.).

(3) *Upland Forests*

The forests covering the bleaker upland areas are predominantly coniferous, although numerous deciduous trees, mostly beech and ash, occur on the lower slopes. Three main altitudinal zones may be distinguished which vary in height with the latitude of the upland. They comprise a lower zone of firs, pines and beech, a middle zone of larch and Arolla pine, and an upper zone where occur alpine meadows, bushes and isolated dwarf trees. As a rule, however, the tree-line is clear-cut and distinct.

In the Central Massif the main forests, occur between 600 and 800 m. and the upper tree-line is at about 1,200 m. The summits of the uplands range from 1,400 to 1,886 m. and are covered with alpine pasture. Besides a variety of pines, the beech dominates in the Morvan and Montagne Noire, and the sweet chestnut flourishes on the crystalline rocks.

In the Vosges and Jura the tree-line is at 1,200-1,300 m.; beyond this are summit moorlands and pastures devoid of trees. The forests of conifers are extensive on the plateaux from about 700-800 m., while deciduous trees, including maple, plane, mountain ash, mountain elm and beech, are scattered on the lower slopes (Plate 36).

In the Alpine regions the upward tree limit varies considerably according to aspect and district, from about 1,800 to 2,400 m. In the damper northern section the chief tree is *Picea excelsa*, while species of fir cover the valley sides and the lower pre-Alp summits. Below 1,000 m. occurs a mixed coniferous and deciduous woodland, including maple, elm, ash and birch. In the southern section the larch is much more abundant, but the fir and beech are less frequent because of the diminished moisture. The larch, Arolla pine and evergreen alder are often found near the upper limit of tree growth. The woods are less extensive than in the northern section.

The higher forests of the Pyrenees are similar to those of the Alps, the lower ones similar to those of Provence. The tree-line varies between 2,000 and 2,400 m. The cork oak forms extensive evergreen woods on the lowest slopes; higher up, where there is more rain, are dense thickets of kerm oak; chestnuts and beech grow up to 500 m.

with here and there ash and elm; varieties of fir and pine occur up to the tree limit.

Afforestation Policy

The extensive planting of trees as part of a definite state policy has been carried out in many parts of France in both upland and lowland areas. This afforestation has aimed at reducing the country's extensive imports of soft woods and pulp, at making good the forest areas ravaged in the last war, at fixing the sand dunes of the Landes and at combating rain wash and torrent erosion. Conifers are used almost exclusively for artificial plantation as they will grow in almost any physical environment, will reach maturity relatively quickly and will yield a variety of products. The upland areas so planted are chiefly in the Alps and the Central Massif, while outstanding lowland plantations are in the Landes, the Sologne and the *Champagne pouilleuse*.

In the *Alps* afforestation began in 1860 as a defence against soil erosion. By 1929, the state had purchased 189,768 ha. of land and had planted 110,000 ha. of these. A further 89,660 ha. are on schedule to be purchased as future state forests. An additional 32,000 ha. have been planted by individual owners with state help. In the Alps few extensive single state forests have been planted, as no arrondissement or commune is unwooded and afforestation usually takes the form of connecting scattered natural forest.

In the *Central Massif* the most notable work has been done in Aigoual south of the Cevennes, where between 1856 and 1931 the state acquired and planted 13,766 ha. Five-sixths are conifers, but beech, chestnut, ash and some varieties of oak have also been planted. The state delivered 65 million young trees between 1863 and 1933 from the nurseries in the Rhone valley to various communes in the Massif. In the Puy-de-D6me 22,000 ha. were planted between 1843 and 1934. On the Montagne Noire and the plateau of Millevaches (Limousin) future afforestation schemes aim at planting some 90,000 ha. of the total uncultivated area of 110,000 ha.

The *Landes*, which consist of sand dunes, marsh and gravel soils, were very scantily wooded from ancient times. At the end of the eighteenth century there were only a few scattered maritime pines and some dwarf oaks. The physical nature of the terrain made cultivation impossible. In 1783, a few experiments were made with little success, but in 1857 drainage by canals was begun in some places. In 1862, the department of *Eaux et For its* was given charge of the area to combat the invasion of the dunes. A dune wall 8-15 m. high

was built along the coast, about 150 m. behind the highest tide-mark. The hinterland was planted chiefly with maritime pine, and smaller plants were used to fix the terrain. This woodland now covers 956,000 ha. and is by far the largest and most continuous forested area in France (Fig. 59). Owing to a high resin content, the trees are not suitable for pulping; this resin is collected and forms a valuable product (Plate 37). The thinnings are used as pit-props; larger trees when injected with copper sulphate make durable sleepers; mature trees are utilized as constructional timber of all kinds. The necessary drainage has transformed the unhealthy malarious moorland and fen. Population is of course still small, as forestry maintenance does not require many employees, although there are open areas where maize is grown and dairy cattle reared.

The *Sologne* is covered with coarse sand which often lies on clay, and marsh with shallow sheets of water is common. An ancient forest of deciduous woods covered half of it in past years, but by 1800 it had been reduced to one-tenth of its former size. By 1830, however, the forest as a result of planting covered 120,000 ha., of which 72,000 ha. were coniferous. In the winter of 1879 and 1880, a disastrous frost killed most of the maritime pines, so when reafforestation began again other varieties of pine were first used and then Douglas fir. By 1914, the *Sologne* had 170,000 ha. of timber, but nearly half was felled during and immediately after the war of 1914-18. Although afforestation began again, in 1930 the total of 159,000 ha. was still substantially below the pre-war level; another 90,000 ha. are scheduled for planting.

The *Champagne pouilleuse* is over 700,000 ha. in extent; it is little cultivated as the soil is thin and chalky, and the land is utilized almost solely for grazing. Much work has been done by private initiative and many thousands of hectares have been planted with pine, birch, willow and alder, and with oak on the better soils. By 1914, 100,000 ha. had been planted, but these suffered badly owing to excessive felling during the war of 1914-18. Planting now has almost made good the losses.

The *Verdun district* in Lorraine was also terribly devastated during 1914-18. Even the rock was sometimes bared by explosives, and 14,000 ha. of forest were destroyed. By 1938, 12,400 ha. had been reafforested.

Plate 36. The timber industry in Alsace

THE VICHY REGIME

The harvest of 1938 was good, and large surpluses of wheat and other cereals were stored for possible national emergencies (see p. no). In 1939, the areas under crops showed a small decrease, due largely to the disruption of economic life by the mobilization of September-October 1938. When final mobilization began in August 1939, the harvest was in progress. Although delayed considerably by the immense drain of man-power from the land, it was completed by older men and youths, by women, and in some areas by troops released for the purpose. The season was reasonably good; the areas of crops were usually well below the record high yield of 1938, but in general up to the average. The following table gives the areas and yields of the commodities for which figures are available; the 1938 figures are appended for comparison:

	938		1939	
	Area 1,000 ha.	Yield 1,000 quintals	Area 1,000 ha.	Yield 1,000 quintals
Wheat	5,050	98,010	4,727	78,000
Barley	759	12,907	799	9,980
Rye	631	8,111	648	8,060
Oats	3,245	54,574	3,242	43,540
Maize	340	5,786	329	5,230
Potatoes	1,425	173,145	1,382	150,000
Sugar beet	319	79,800	333	85,000

From official sources.

The armistice of June 1940, with its division into occupied and unoccupied territories, upset the internal agricultural equilibrium of the country. The north, where most of the wheatlands are situated, had to bear the burden of the German army of occupation; the hilly south could not feed itself in normal times. Only in Alsace-Lorraine, which was *de facto* incorporated into the Reich, and in the north-eastern plains did the Germans make any substantial effort to assist agricultural recovery. The agricultural situation was made worse by the large number of men held as prisoners of war, by the slaughtering of livestock for the army of occupation, by the shortage of fertilizers and vine sprays, and by problems of transport and distribution. The bad harvest of 1940, together with the increasingly close blockade, produced a considerable shortage of food during the winter of 1940-1; rationing of bread, sugar, butter, meat, wine, cheese, fats, potatoes, macaroni, rice and pulses was imposed. In spite of efforts by the Vichy government, the food situation continued to be critical,

and the winter of 1941-2 was a hard one for both unoccupied as well as occupied France.

The problem of food supply was naturally much more acute in the towns than in the country, and various schemes attempted to equalize distribution. Farmers were urged to co-operate with the government; quotas were levied, and bonuses paid for prompt supplies; rigorous measures were taken against the 'Black Market'. Illegal trading in foodstuffs became a vital social question in France; it was stated in December 1941 that supplies coming on to the 'Black Market' were as great as or greater than those reaching the legal markets. Large-scale hoarding by peasants was severely punished but with little effect. Malnutrition, especially among children, was very prevalent in the towns; the death-rate rose, and infantile mortality during the first half of 1941 trebled. Trouble culminated in the food riots of January 1942; they occurred chiefly in the southern departments of Hérault and Gard, where even the small rations could not be obtained. Supplementary rations were issued here and elsewhere.

The situation was helped slightly by shiploads of powdered milk, wheat and other supplies from America during 1941, which were allowed through the blockade by Britain on condition that the American Red Cross and American Friends' Service Committee guaranteed that the supplies should not fall into German hands.

The Harvests of 1940-1

Wheat (see pp. 106-10). Over two-thirds of French wheat is produced in the occupied zone. It was estimated that only about 3 million ha. were sown in the autumn of 1939 for the 1940 harvest—over 1½ million ha. less than in the previous year. Destruction of crops by the military operations in the summer of 1940 was not as great as might have been expected, owing to the mobility of the warfare and to the rapid decision. But even so, some wheat was damaged by fighting, and the flight of so many peasant families caused destruction by neglect. Much of what remained was harvested with the help of the German army. To the south, in the unoccupied zone, the harvest was the worst for many years. The total French crop of 1940 was about 42,500,000 quintals—as against the normal 75 million quintals. As a result, in October 1940 strict bread rationing was imposed in both the occupied and unoccupied zones.

In the autumn of 1940 some 4,100,000 ha. were sown, a 30 % increase on the previous year. During the early summer of 1941 small amounts of wheat went from occupied to unoccupied France,

but these were far below what was needed (the deficiency was estimated at 7-8 million quintals in the unoccupied zone), and at the end of May unoccupied France faced extreme hunger. The bread ration was decreased and adulterants were introduced into the flour. The Germans, however, released 2 million quintals out of supplies requisitioned for the army, and this enabled 3 million quintals to be sent by a barter agreement from occupied to unoccupied France; 700,000 quintals were imported from North America, and 145,000 quintals came from America. At the end of June 1941, the bread ration was restored to a normal level (275 grm. or less than 10 oz. per day). The 1941 crop was estimated to be about 65 million quintals, which was more than in 1939 but still well below average.

Other cereals (see pp. 110-13). Nearly all the *oats* are grown in northern France. The harvest of 1940 was poor and totalled only 30 million quintals, or about three-quarters of the 1939 yield. In 1941, the yield improved to about 35 million quintals. The amount used as fodder was drastically reduced, and Germany requisitioned large quantities. The poorer cereals, *millet* and *rye*, which are mainly grown in unoccupied France on the Central Massif, were a little below normal in both years, but they feed only a small proportion of the population. The Germans claimed an increase in the acreage of rye in the occupied zone. Most of the maize comes from unoccupied France. Some 3,400,000 quintals were harvested in 1940, that is, just over half of the previous year's total. No figures are available for the production of *barley*, but here again the Germans claim an increase in 1941 in the occupied zone; this cereal follows the trend of the wheat yield quite closely, so that the 1940 crop may be estimated at 4-5 million quintals, with about half a million more in 1941.

Potatoes (see p. III). The potato crop of 1940 amounted to about 90 million quintals, and in 1941 to about 120 million quintals; both compare unfavourably with the average pre-war yield of about 160 million quintals. In many parts of France potatoes form a staple part of the diet, and a shortage has serious consequences. In September 1941, the government tried to supplement the insufficient rations of bread and meat by as large a ration of potatoes as possible. Compulsory purchase quotas from producers were introduced, and fanners who refused to sell their quota to the government became liable to three years imprisonment. A bonus of 5 fr. per quintal was paid, and urgent appeals for co-operation were made so that requisitions would not be necessary. The Germans distributed small quanti-

ties of potatoes in 1941, ostensibly from their own but more probably from French stocks.

Sugar beet (see pp. 111-13). Almost all the land under sugar beet and all the refineries are in occupied France; the crop suffered considerable damage during the war and there has been a great shortage of sugar, with resultant stringent rationing. In 1940, only 114,000 ha. were harvested from a planted total of 271,000 ha., and the total produced was estimated at 46 million quintals; this figure compared very unfavourably with the 1938 total of nearly 80 million quintals. There was some improvement in 1941, and the output was estimated to be nearly 70 million quintals. The sugar ration in unoccupied France remained at 500 grm. (about 17 oz.) monthly, but that figure was still much below the peace-time consumption.

Wine (see pp. 113-18). The total yield of wine was about 85 million hl. in 1939; in 1940 and 1941, it was estimated to be about 60 and 45 million hl. respectively, which compared unfavourably with the normal average of 70 million hl. Most of the French fine wines, with the exception of those produced in the Burgundy district, come from occupied France. Most French *vin ordinaire* comes from the unoccupied zone, and this output has not been appreciably reduced. It was estimated that 10 million hl., or about one-sixth of the total peace-time output, were requisitioned during 1940 for the German army of occupation. The grapes of the famous vintage areas were grown and processed more casually to produce cheap wines for general consumption.

The industry suffered greatly in 1940 owing to the shortage of skilled labour, and the grape harvest was rarely completed. In 1941, disease was widespread due to the lack of copper sulphate for spraying; in Burgundy, for example, the grapes were almost completely ruined by mildew. On the other hand, vine growing in Alsace has benefited; the area of vineyards in 1940 was 16,000 ha., nearly 1,000 ha. more than in 1939. This development of Alsatian agriculture has been part of German policy. The 30,000 families engaged in viticulture have gained by the elimination of cheaper French wines, which had steadily reduced the Alsatian vine area in pre-war years.

In September 1940, the Vichy government introduced new regulations for vine growers. Every vineyard of more than 5 ha., or producing more than 500 hl., was obliged to grow crops other than vines on one-tenth of its land. Growers producing more than 200 hl. were to keep 20 % of their grape 'must' for turning into sugar, and those producing more than 50 hl. of pure alcohol had to keep the

grape pips for the production of vegetable oil. There was much trouble during 1941 over the distribution of wine, resulting in a clash between the interests of the growers and the government's wine policy. Wine growers asked for higher prices, for more government assistance, and for less requisitioning. General suspicion attributed the shortage of supplies to the sale of requisitioned wine by Germany through neutral firms in Switzerland and Portugal to America. The official explanation was that production for 1940-1 had been abnormally low while consumption had increased, and little had come from Algeria owing to transport difficulties. Severe rationing was introduced at the end of 1941; normal consumers were allowed 1 l. a week and heavy workers 5 l.

Other crops (see pp. 118-20). Efforts were made to increase the cultivation of vegetables generally—of haricots, of soya beans and of other oleaginous plants, of flax, of hemp and of green feeding stuffs. The chief disabilities were shortage of labour, of seed, of fertilizers, and of tools. The only conspicuous increase has been in the case of flax; the area of this crop was 65 % greater in 1941 than in 1938. Otherwise only in Alsace-Lorraine, where the Germans have supplied these wants, was produce up to pre-war standard. The development of agriculture in Alsace-Lorraine was dominated by Germany's needs; the area under tobacco, for example, was maintained by the German tobacco firms which purchased and prepared the entire crop. The winter cultivation of oil seeds (including rape), which had been negligible before the German regime, was increased to 1,900 ha. in 1941 and to 3,500 ha. in 1942. On the other hand, hop cultivation was reduced by 1,000 ha. to avoid competition in the German market.

Livestock (see pp. 120-6)

The majority of *cattle* in 1938 were in the north (see pp. 120-4 and Fig. 48), but large numbers were slaughtered to supply the army of occupation, which drew a large part of its meat from France. Shortage of imported feeding stuffs also caused extensive slaughtering. Unoccupied France in 1938 had only about a quarter of the total French cattle, chiefly dairy herds in the Central Massif, Alps and Jura. It was estimated that even if the total number of milch cows had not declined, the milk output would have been reduced by 15-20 % because of the shortage of oil cake and of other feeding stuffs. Thus there was a great shortage of milk, cheese and butter. In September 1940, cattle were redistributed to compensate areas where herds had been destroyed owing to the war. The German authorities tried to

replace the Lorraine livestock which had been destroyed during hostilities by importing animals from Germany, Holland and Denmark, and in December 1940, 11,000 head of cattle bought from Switzerland and Austria arrived in Strasbourg. Efforts were made in unoccupied France to grow lucerne and roots for fodder. Nevertheless, the total number of cattle in both zones decreased by 25 % between September 1940 and April 1941; in August 1941, it was stated that the herds consisted mainly of young animals which would not be suitable for slaughtering for a long time. By the summer of 1942, the herds of cattle had increased in number compared with April 1942, but the major difficulty continued to be shortage of feeding stuffs.

It was estimated that there was a deficit of only 130,000 *horses* (out of a total of 2½ million) after the armistice, but the German army requisitioned large numbers, and petrol shortage increased the need for horse transport. This deficit was reduced slightly during the winter of 1940-1 by transfers from the army and by imports from Algeria. There is little information about any other livestock, except that in July 1941 the numbers of *pigs* and *sheep* arriving at the Paris market of La Villette were respectively one-quarter and one-half of the total in the same month in 1938. This is probably indicative of peasant hoarding, although the number of pigs in 1941 was some 33-40 % below the pre-war level, due to slaughtering for immediate needs, while sheep were about 15 % below.

The government in September 1941 tried to improve the meat situation by organizing fodder supplies. A plan was drawn up specifying the amounts of barley and oats which each department had to deliver to the departmental agricultural committees for distribution among communes according to the needs of each region. Bonuses were given for quick delivery, and farmers who undertook to carry out government contracts for stock breeding received extra rations of fodder. Nevertheless, the meat ration for January 1942 was cut from 250 grm. (about 8½ oz.) weekly to 180 grm. (about 6oz.) in the towns, and to 125 grm. (about 4oz.) in the country; the extra meat ration for heavy workers remained the same. The cheese ration remained at 50 grm. (under 2 oz.) per week, and all fats remained at 450 grm. (under 1 lb.) per month.

Forests (see pp. 135-42)

After the armistice, the department of *Eaux et Forêts* had to face a large increase in timber consumption. This was due to an almost

complete cessation of timber imports, and to the necessity of using wood in large quantities to be made into charcoal for producer-gas engines, to manufacture cellulose needed by the greatly increased artificial textile industry, to manufacture wooden shoes because of the leather shortage, and as domestic fuel, as well as for all its normal uses of carpentering and furniture making. It was estimated that the amount of wood used directly or indirectly as fuel increased from 14'8 million cu. m. in 1939 to 30 million in 1941, and that the monthly production of charcoal increased from 15,000 tons before the war to 52,000 tons by the end of 1941.

Soon after the armistice, government forestry camps were established to fell timber on a large scale, and a law of August 1940 obliged all forest owners to increase by 50 % the number of trees they normally felled. During 1941 enormous areas of forested land were cleared. But it was increasingly apparent that this was leading to critical deforestation with its resultant evils of floods, soil erosion and avalanches, as well as to grave shortage in the future. Accordingly a law was passed in January 1942 to deal with reafforestation. It provided that from 250,000 to 300,000 ha. should be planted with trees during the next decade, particularly in the Landes, the Montagne Noire and the Millevaches plateau of the Central Massif. Certain districts would be delineated for compulsory planting, and the land-owners would be given the choice either of doing the work themselves with the aid of state subsidies, or of allowing the department of *Eaux et Forêts* to do it.

Labour and Land

An acute shortage of agricultural labour was experienced after the outbreak of war, because the agricultural population was mobilized far more drastically than the industrial. After the armistice the shortage was still worse, as of 1,800,000 prisoners taken by the Germans 1,200,000 were agricultural workers, and few of these have been released.

German Measures. German plans for French agriculture paid less attention to the needs of the French than to the need of a comprehensive plan to increase production through a more intensive exploitation of French resources. France had to supply a large part of European foodstuffs—chiefly fruit, vegetables, wine, wheat, oleaginous plants, flax and hemp. The Germans released prisoners in the occupied zone, and soldiers from the German army were used as farm labourers. The abandoned farms of north-east France were ordered to be

cultivated, and detailed instructions as to which crops were to be grown were issued. German overseers were appointed to farm large tracts of abandoned land, using large-scale mechanization. The Germans also ordered much land in the Maginot area, deliberately left derelict for many years, to be cultivated; it is estimated that about 50,000 out of 150,000 ha. were put under cultivation. Many of the people of Lorraine were assigned to abandoned or uncultivated land with a view to permanent settlement as part of the German effort to develop Alsace-Lorraine. Other measures included credit and loan facilities to assist the financial burdens of reconstruction, and agrarian taxes were lightened pending full recovery. In return for this assistance, the Alsatian farmers were required to produce crops in accordance with German plans.

Vichy Policy. French agricultural policy was dominated by two main objects: first, to supply the country with food and to keep down food prices; and second, to assist the farmers in every way possible and thereby strengthen the economic structure of the country. These policies have been carried out in both zones as far as possible, but to a much less extent in the occupied area. The Vichy government instituted a series of measures to meet the situation in the territory under its control, but most of these, however, have not been implemented.

Attempts were made to stimulate a 'back to the land' movement. All agriculturalists and rural artisans were as far as possible demobilized first. Agricultural Associations assisted in the repatriation of people to their lands, and in September 1940 2 milliard francs were advanced by the Treasury through local branches of the *Credit Agricole* to assist farmers in repairing war damage. Each commune was required to complete within two months an inventory of land left uncultivated for more than two years. The prefect of each department was then authorized to grant such land for a period of nine years to any person of French nationality who could offer adequate guarantees. Preference was to be given to relatives of men killed in the war. No rent was to be paid for the first three years, and after that it was to be only one-half that of similar farms in the same district. Farmers were encouraged to take school leavers, especially those from urban areas, as apprentices; there were 6,000 of these in 1941. The state promised to pay the farmer a subsidy of 900 fr. towards their training. Compulsory land service was instituted for young people between 17 and 21 as a temporary measure. In July 1941, a law was passed requiring the compulsory attendance of all

boys and girls not receiving other education at special agricultural courses. The state also assumed powers to requisition men, preferably urban unemployed with agricultural experience, and to draft them on to the land.

A large government works programme for agriculture was set forth in October 1940. It included schemes of electrification, water supply, drainage and land reclamation, and the building of co-operative factories and dairies. Schemes for land reclamation included the development of the Sologne district, and the reclamation of the Crau district in the Rhone delta by the *Compagnie Nationale du Rhone*, to which subsidies have been paid by the state.

Several measures concerned with the organization of the workers have been effected. In December 1940, an agricultural corporation was outlined, providing for the organization of all farmers and agricultural labourers into local unions within each region (see vol. II, pp. 265-71). These regional organizations were to be coordinated by a national committee. Specialized organizations, insurance and credit societies, and co-operatives, were all to be included within the framework of the agricultural corporation. During the winter of 1941-2 a committee of the *Conseil National* was engaged in drawing up the charter of the Peasant Corporation. The importance of the family holding and the development of modern methods through agricultural unions and co-operatives was emphasized. Official policy aimed at reducing the number of farm labourers by giving them holdings. Subsidies were granted towards the improvement of rural housing.

The Vichy government also made some effort to tackle the problem of divided inheritances (see pp. 132-4), and of the reorganization and regrouping of agricultural holdings. It was clearly impossible to carry out a policy of land resettlement in districts where each farm consisted of many scattered strips. In April 1941, a law was passed whereby the prefect could initiate schemes in any department without the previous necessity of obtaining the consent of a village majority. In each commune strips of land were to be grouped into more compact holdings by a committee appointed by the prefect. No strip after regrouping was to be more than 3 km. away from the farmstead. State help was given to provide new buildings for family holdings. In July 1941, the inheritance code was modified to allow small farms to remain undivided at the request of one of the co-heirs.

As a result of all these efforts, it was stated in May 1941 that nine-tenths of the land abandoned in 1940 had been brought back to

cultivation, and that since July 1940 the state had advanced 200 million francs directly to farmers and a further 200 million francs to Agricultural Credit Societies for reclaiming waste land.

BIBLIOGRAPHICAL NOTE

(1) Statistics, used both in the text and in the compilation of the maps, are given in two French official publications—the extremely detailed *Statistique Agricole Annuelle* (Paris) and the more summary *Annuaire Statistique* (Paris). Statistics relating to the agricultural population are given in detail for 1931 in vol. 1, part 3, of the French census, *Résultats statistiques du recensement général de la population en 1931* (Paris), and in a more summary form for 1936 in vol. 1, part 1, the only section so far published.

(2) General descriptive surveys of French agriculture are given in P. L. Yates, *Food Production in Western Europe* (London, 1940), part iv; in H. Ormsby, *France, A regional and economic geography* (London, 1931); in the *Report on France, Department of Overseas Trade* (H.M.S.O., London, 1934); and in L. Michael, *Agricultural Survey of France* (U.S. Department of Agriculture Bulletin, No. 37, Washington, 1938).

(3) Useful accounts of special regions or of aspects of agriculture are numerous; they include French government pamphlets, notably the *Monographies Agricoles* published by the French *Ministre de l'Agriculture*, the publications of the *Conseil National Economique*, and regional monographs by French writers.

Chapter IV

FISHERIES

Introduction: The Eastern English Channel: Normandy and North Brittany: South Brittany: The Bay of Biscay (south of the Loire): The Mediterranean Coast: Organization and Research: Bibliographical Note

INTRODUCTION

In view of the extensive coastline of France, it is not surprising that the French fishing industry employed in 1937 nearly 70,000 registered boat fishermen (*en bateau*), and about 50,000 part-time shore fishermen. Another 9,000 people were also employed in the preservation of fish and in associated activities; two-thirds of these were women.* Although the fishermen were distributed widely round the coasts, the table on p. 155 shows that the majority lived on the Atlantic coast south of Brest, and that three ports, namely, Concarneau, Lorient and Boulogne, had together nearly one-quarter of the fishermen of France.

The total catch, other than shell-fish, in 1937 was 352,000 metric tons, which compares unfavourably with that of other European countries, as the following table shows:

	1,000 metric tons		1,000 metric tons
Great Britain	1,108	Holland	263
Norway	1,012	Denmark	88
Germany	671	Finland	22
Iceland	322		

Two-thirds of the total French catch by weight is made up of five species offish—cod, herring, sardine, mackerel and tunny; yet 'other products', including finer varieties and shell-fish, form half to three-quarters of the total value, as the following table shows:

	Million francs	
	Total value of all fish	Value of ' other products'
1932	958	663
1933	927	597
1934	893	544
1935	761	516
1936	892	720
1937	1,142	674

* These figures refer to mainland France. Corresponding figures for Corsica and North Africa are included separately in the table on p. 155. It is not possible, however, to isolate the figures of Corsica and North Africa in the tables of total values and weights of individual fish on p. 156.

The proportion of the value of 'other products' was lower in 1937 than for many years, because of the unusually heavy catches of cod, herring and sardines (Fig. 60). This total of 1,142 million francs (to which Corsica and North Africa contributed 88 million francs) was just under one-third the value yielded by the coal mines of France, but it was only one-fiftieth the value of French agricultural produce. The corresponding British fishery figures for 1936 were approximately one-tenth for coal mines and one-twelfth for agriculture.

Fig. 60. Annual French catch of cod, herring, sardine, mackerel and tunny, 1920-37

From *Annuaire Statistique*, 1938 (Paris, 1939).

'Wet fish', as distinct from 'shell-fish', fall into two main classes—pelagic and demersal. The former live in surface waters or at no great depth, and occur in large shoals in the relatively shallow seas on the continental shelf. The more important of these in the French fisheries are the herring, sardine, mackerel and tunny, and the quantities

The source of this and of other tables in this chapter was *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

caught vary tremendously from year to year (Fig. 60). In 1937, the amounts of each were as follows

	Weight metric tons	Value million francs
Herring	64,682	88
Sardine	38,310	125
Mackerel	21,299	62
Tunny	10,658	54
Anchovy	7,547	10
Sprat	2,742	3

Demersal fish live normally at the bottom of the sea; this category includes both flat fish, such as plaice and sole, and free-swimming varieties, notably cod and whiting. Cod is the most important, both by weight and value, but a great variety of other demersal fish is caught. In 1937, the following quantities were landed:

	Weight metric tons	Value million francs
Cod (excluding oil)	65,512	154
Whiting	26,843	71
Skate and ray	14,068	37
Plaice	7,935	29
Sole	1,577	28
Congers	2,846	11
Turbot	1,203	11
Mullet and bass	1,139	11
Eels	1,025	4
Brill	417	4

In addition to these two main categories, the French official returns also include a total of 65,144 metric tons (valued at 200 million francs) of 'other fish', that is, of unclassified *poisson frais*, which are sold unsorted in bulk. Shell-fish, which are hardly comparable by weight, were valued in 1937 at 147 million francs; lobsters comprised 38 million francs, oysters 26 million francs, and shrimps 18 million francs. They formed one-tenth of the total value of French fisheries; the corresponding figure for Britain is only one-thirtieth. To these figures must be added large but unspecified amounts of fish which do not appear in official returns. In the first place, these take account only of fish sold in market, and the amounts consumed by the fishing population itself must be considerable. In the second place, inland and fresh-water fisheries (rivers, lakes and artificial pools) provide an important source of food in country districts.

During the last forty years the French fishing industry has experienced, but to a much less extent, the same centralization and industrialization, which has concentrated the British fishing industry at six main ports. Half the total French catch is landed at four

ports—Boulogne, Lorient, Dieppe and La Rochelle (Fig. 61). The first of these is pre-eminent; over a quarter of French fish are landed there, but even so it handles less than one-third of the annual total of Hull. If the value of fish is considered instead of its weight, Boulogne is still outstanding but less strikingly so, as it is responsible for about one-sixth of the total value.

Fig. 61. Weights of fish landed per annum at French ports, 1937

Based on the *Atlas de France*, Plate 53 (Paris, 1936), with statistics brought up to date from *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

In 1937, there were more than 23,000 fishing craft registered along the French coast, including about 1,500 in Corsica and North Africa. Of this total, only 401 were steam-driven, 11,373 were mechanically driven by Diesel or by auxiliary motors, and 9,711 were sailing boats. The first category, however, amounted to over 92,000 metric tons, or more than one-third of the total fishing tonnage. It is significant

to compare (p. 155) the number of vessels and their total tonnage at Boulogne, Lorient and Fecamp, where most of the large steam trawlers have their base, with ports like S&te, Les Sables d'Olonne or Arcachon. Sete, for example, has more than three times as many craft as Boulogne, but the tonnage of the latter is ten times as great.

The French fishing centres may be conveniently grouped in five areas, as follows:

- (1) The Eastern English Channel.
- (2) Normandy and North Brittany.
- (3) South Brittany.
- (4) The Bay of Biscay (south of the Loire).
- (5) The Mediterranean Sea.

In each stretch of coast the fisheries will first be described, then the important fishing ports.

THE EASTERN ENGLISH CHANNEL

This area is characterized more than any other part of the French coast by the centralization and commercialization of the fishing industry. There are few little villages, such as are typical of Brittany, whose populations earn their livelihood by small-scale and often part-time fishing. Instead, there is a small number of fishing ports able to provide accommodation and fuel facilities for the large mechanized vessels. More than one-third of the total French catch is landed at these ports.

Herring. The entire French catch of herrings, about one-tenth of the European total, is landed along this coast. Herring fishing starts in May in waters to the east of the Shetlands; it has migrated to the seas off Flamborough Head by October, and reaches the Straits of Dover and the Channel in November. Formerly, the typical vessel was the *dundee*, a strongly built sailing boat of from 10 to 60 metric tons, but there is an increasing number of steam or Diesel drifters. These drifters are some 40 m. long, are of about 300 metric tons, and carry a crew of from six to eight. The herring are caught at night by series of drift nets (*raies*), each 50-60 m. long, which form an extended wall of netting kept vertical in the water by buoys and weights, and fastened by a series of ropes to a headline which is attached to the drifting ship. A large amount of herring is caught by trawling in the day time, that is, by dragging along the sea bottom a bag-shaped net kept open by a beam or by wooden trawl boards (*chalut a panneaux*). This takes place off the Shetlands

Plate 39. *Terreneuvers* at St Malo

St Malo is the home base for the *terreneuvers*, which fish for cod off the Grand Banks of Newfoundland. The vessels in the Bassin Duguay-Trouin are decorated with bunting for a religious ceremony before they leave in March for St Pierre and Miquelon.

Plate 40. Fish preserving at Concarneau

Large numbers of women are employed on a part-time basis in the numerous sardine and tunny preserving factories of the town.

Plate 41. The sardine fleet at Douarnenez

This view shows part of the large flotilla of *bateaux sardiniers* in the Grand Port. The fine meshed nets with their cork floats are hung from the masts to dry.

Plate 42. Tunny boats at Concarneau

The usual tunny boat is a strongly built *dundee* of some 40-60 tons; a notable feature is the *tangon* or rod, fastened to the base of the mast, to which the lines and hooks are attached.

from December to May, off Aberdeen from May to October, and in the seas off the north of Ireland and in St George's Channel from July to September (Fig. 62). It is a harmful (although lucrative) practice, as it spoils the grounds for other varieties of fish.

Mackerel. Many of the herring drifters are used at appropriate times of year for the mackerel fishing. The mackerel are caught in March off the south coast of Ireland, and the season ends in June off the Scillies. Thus the drifters are laid up only from January to March, and sailors sign under a single contract for about nine months.

Cod. Fecamp and Boulogne are the two chief centres for the cod fisheries or *grande peche*. These lie in distant waters off Iceland, Greenland and Newfoundland, and more recently in the Barents Sea. The amount of cod produced in 1937 was as follows:

Ground	Fish metric tons	Oil hectolitres
Iceland and north European waters	11,678	1,742
Greenland	15,280	5,390
Newfoundland	38,554	9,017

French fisheries in Icelandic waters were once very extensive, and vessels sailed not only from Gravelines but from Paimpol and St Malo on the Breton coast. In 1900, over 250 sailing boats, including both *dundees* and *goellettes* (a type of schooner), fished these waters, but in 1932 there were only twenty-one, including nine from Gravelines. These vessels left France about the middle of February, and reached Iceland in about 10 days. The *dundees* fished the east coast of Iceland from March to August, moving gradually north, while the schooners similarly worked northward round the west coast. The decline in the French Icelandic fisheries coincided with the disappearance of these sailing vessels, which were unable to compete with British and Norwegian steam trawlers. In 1931, only about 3,000 tons of Icelandic cod were caught.

Since that year there has been a revival, owing to the increase in the number of French steam trawlers built at Havre or in some cases at British dockyards. They are owned by companies such as *La Morue francaise* or *Pecheries de France*. Stationed at Fecamp and Boulogne, these vessels are from 550 to 1,350 gross tonnage, have a bunker capacity of 250 tons, and a storage space of about 750 cu.m. They leave port at the beginning of February, fish to the south and west of Iceland, and return in April and May either to France or to Reykjavik. In the latter case the catch is transferred to a carrier ship, and the trawlers, after revictualling and refuelling, proceed to the Grand

Banks of Newfoundland or to the west coast of Greenland for a second season.

At these fishing grounds they join the small fleet of vessels, including sailing craft such as *terreneuviers* or *trotsmats*, stationed at St Pierre and Miquelon, which are the last remnants of the former American colonial empire of France. The French were the pioneers of the Newfoundland fisheries, and in the seventeenth and eighteenth centuries supplied vast quantities of salt and dried cod to Catholic Europe. Certain fishing rights enjoyed after the Treaty of Utrecht in 1713 were renounced under a convention concluded with Britain in 1904. They are now allowed to fish the banks off the coasts of Newfoundland from Cape St John on the east coast round to Cape Ray in the south-west.

Each vessel carries twelve or more little row-boats or *doris* which leave at dawn with two men. Series of lines each with several hundred baited hooks are laid and marked by buoys; the *doris* then return to the ship and the crews spend the day cleaning and salting the previous day's catch. The livers of the fish are usually packed in barrels, but on the most modern vessels the liver oil is extracted on board; the roes are salted, and the offal is converted into fish manure. In the evening, the *doris* go out again to collect the catch.

Miscellaneous fish. A large amount of miscellaneous fish, known as *poisson frais*, is landed at ports along this coast by small and medium-size trawlers, which put out for six or seven days to fishing grounds in the English Channel, St George's Channel, and the seas south of Ireland. There is no specialization; the boats not only bring in turbot, brill, sole, skate, etc., but also take part in the mackerel or herring fisheries. This provides regular employment throughout the year, although the returns are tied up with fluctuations in demand; a good haul in Lent, for example, will produce higher profits than at other times of the year.

Boulogne (Plate 38) is easily the biggest fishing port in France, both for the weight and value of catch, and also for the total tonnage of its boats (see p. 155). Six docks serve the fishing fleet, but the port facilities are insufficient and expansion of quay space is virtually impossible.* In recent years there have been improvements in facilities for curing, salting, and packing, and fast night trains of refrigerator cars provide a good service with the Paris markets. Over 5,000 people, or about

* Details of the facilities (docks, quays, sidings, etc.) at the larger ports mentioned in this chapter are given in chapters 1, 11 and in of volume iv of this Handbook.

one-tenth of the population of the town, find occupation in the activities associated with fish curing, etc.

Dieppe. Although Dieppe handles only about a quarter of the tonnage of Boulogne, it is an important port for the smaller trawlers which fish for *poisson frais*, returning daily to supply the markets. These boats use the outer port (apart from the packet quay) and the Bassin Duquesne. A large covered fish market, with modern equipment and adjacent railway sidings, has been built on the He de Pollet, near the oiler port, and less than four hours elapse between the docking of the fishing boats and the loading of washed fish into refrigerator cars. Sometimes as much as 200 metric tons of fish arrives in the harbour between 1500 and 2100 hours and leaves before midnight for Paris, either in one of the seven daily fish trains or in refrigerator vans coupled on to a Paris boat train.

Fecamp. Geographical conditions are against the development of Fecamp, as the port is naturally poor, and the lines of communication with Paris are unsatisfactory. Yet it is the fourth fishing port of France in value of catch, because it is the chief centre for the fitting out of the big Newfoundland trawlers, and it has the largest single dried cod market in the country. It takes part also in the mackerel and herring industries.

Gravelines has long since lost the importance of days when it shared, with Paimpol, the Icelandic fishing industry. It now has only a few small boats which fish near the coasts.

NORMANDY AND NORTH BRITTANY

While the northern and southern coasts of Brittany are physiographically very similar, there are considerable differences in their respective fishing industries. On the north coast, fishing is represented by the remnants of a once flourishing deep-sea industry, together with part-time coastal fishing that ekes out the meagre resources of the land. On the south coast there are important sardine and tunny fishing centres. In many of the innumerable tidal creeks along both coasts is a little fishing village, and almost all the population gain a large part of their living from the sea. As a result, Brittany has long been the main recruiting centre for the French navy. Nearly one-half of the personnel of the navy are of Breton origin—some 27,000 out of 59,000 in 1935; and about 23,000 out of the 65,000 of the French mercantile marine are also Breton. Some 42,000, or over a half, of the French fishermen are Breton, and of

these about 38,000 live and work in Brittany itself. The rest have migrated to the big trawler ports of Boulogne, Fecamp, etc. In 1933, there were over 8,000 unemployed deep-sea fishermen in the three centres of St Malo, St Servan and Cancale. Large sailing boats decreased to about a quarter of their number before the war of 1914-18, and, moreover, steam trawlers require fewer hands.

Coastal fishing. Along the north coast are numerous small fishing villages, whose population engage in coastal fishing for herring, mackerel, conger, skate, turbot, mullet and crustaceans. Sailing boats, with a multiplicity of types and rigs long adapted to the needs of a locality, are used.. Paimpol, for example, had 272 registered boats in 1937 averaging about 9 metric tons, owned by 272 *patron-proprietaries*; only ninety boats were mechanically propelled. This coastal fishing employs part-time men who also own little farms, and is scattered and unorganized. The collection of shrimps and shell-fish is carried on at low tide by women and children.

Lobsters and oysters have greater commercial importance than the miscellaneous coastal fishing, as they are sent in fluctuating quantities to Billingsgate. But with two exceptions, the industry is in no way comparable with the large-scale enterprises of south Brittany and the Biscay coast. These exceptions are the cultivation of oysters in the Bay of Cancale and at Treguier, and the lobster tanks at Roscoff, where crustaceans caught along the Portuguese and Moroccan coasts are stored.

Seaweed. An associated industry of some interest is the collection of seaweed in the mud-filled inlets. Regulated by ancient custom, the *goemon* and *varech* is cut in spring by men in barges, and is sold to farmers for use as fertilizers, or sent to iodine factories.

St Malo (Plate 39). One exception to this small-scale local fishing is at St Malo, although this port is by no means as important as it was in sailing-ship days. With some 19,000 metric tons of shipping, it is the third fishing port of France, and sends trawlers to Newfoundland waters. About one-quarter of the dried cod landed in France in 1937 came into St Malo.

SOUTH BRITTANY

The water of the Bay of Biscay is considerably warmer than that of the Channel, and so the chief fish landed in south Brittany are sardines and tunny.

Sardines. The French catch of sardines is only exceeded in value

by that of cod. The industry developed between 1870 and 1900 at the numerous small ports along the south coast of Brittany. Fishing is seasonal; it generally starts in February in the Gulf of Gascony and works north to end off Finistere in November, but it is most active in summer. The sailing boats are of 7 to 8 metric tons and have a complement of from seven to twelve men. They leave port after sunset, and begin fishing at sunrise, either directly from the boats, or from small *carots* (dinghies) taken by the larger vessels. The fine-meshed drift-nets (*battude*), about 30 x 9 m., are baited with a mixture of cod roe and pea-nut flour, and are allowed to float vertically in the water. As soon as a haul of about 5,000-6,000 fish has been made, the vessels hurry back to port, where the catch is immediately sold to the factories. The fish are rapidly cleaned and sorted by women, and are then dried and dipped into hot oil. After drying again, they are packed in tins. It is interesting to note that the price of sardines depends not on the fish but on the quality of the oil, the best varieties being preserved in pure olive oil, the cheaper in cotton-seed oil.

Tunny. Fishing for the white tunny (*germon*) is concentrated into a short intense season of some 100 days from the beginning of July to the middle of October. As a result, the fishermen have to find winter employment on Boulogne trawlers, or in coastal fishing, or they may even sign for a short voyage on a merchant ship. The industry began at La Rochelle and Les Sables d'Olonne south of the Loire about 1885, but now some 95 % of the catch is landed at Concarneau, Douarnenez, Groix, Port-Louis and Etel, where the chief factories are situated. The tunny boats of the south Breton coast number about 700, and they are mostly *dundeas* of some 40-60 metric tons. In recent years, however, a larger motorized semi-trawler type has been introduced which can be used for winter fishing. The boats, each with a crew of six or seven, are away from 10 to 15 days at a time, and make from six to eight voyages in a season. Long rods or *tangons*, which can be raised or lowered, are fixed to the base of the mast; each rod has six or seven strong hemp lines and hooks baited with horse hair, maize straw, etc. Fishing is best done on a grey day with nearly calm seas, and the boat sails at about 6 knots with the bait leaping about on the surface. When a fish is hooked, it is hauled aboard, killed, cleaned and hung up by the head on trestles. The boats return at intervals to the port, where the fish is auctioned before unloading, and then delivered to the factories along the quays. The whole catch is preserved, and 172 canning factories are found along this coast, out of a French total of 207. Some of

these factories, however, handle both tunny and sardines. The work is done chiefly by women, who work very irregularly, and are paid by the hour. At Concarneau, for example, 2,000 women are employed on a temporary basis (Plate 40). The tunny is largely sent to Latin America, Brazil, Belgium, central Europe and Greece.

Miscellaneous fish. Sardines and tunny are the two staple fish, but they are by no means the only ones. From most of the small ports, *dundees* take part in coastal fishing; they sail out each day for a few kilometres from the coast and fish for about 12 hr. From the larger ports, notably Lorient, motorized vessels carry on a variety of fishing. The bigger trawlers of several hundred tons steam out as far as the Grand Sole Bank to the south-west of Ireland, chiefly for hake, skate and eels. Smaller trawlers confine themselves to distances within 25 km. for sole, gurnard, turbot, etc. Mackerel and whiting are fished by line from small boats, or by nets from larger drifters.

Crustaceans and Shell-fish. Lobsters are caught along the south Breton coast, either by *casters* (wicker pots baited with dog-fish), or by large-meshed nets 100 m. long which are dragged along the bottom in water 50 m. deep. The *langouste*, or spiny lobsters, are fished on the coasts of Portugal, Morocco and Mauretania, and the lobster fishers are often away as long as three months. After a successful trip, a boat may return with 7 or 8 kg. of live lobsters. The catch is stored on shore in masonry tanks at Concarneau, Audierne, Mane-meur, Port-Haliguen, etc. Oysters are cultivated in the silted ria of Etel at Auray, at La Trinite near Carnac, and at Carnac itself.

On the south, as on the north coast of Brittany, there are a large number of small ports and sheltered anchorages, each with some hundreds of craft. Apart from Lorient, the two largest fishing ports in the south are Douarnenez and Concarneau, while the naval port of Brest accommodates over a thousand small fishing vessels.

Douarnenez (Plate 41) is notable in that, in 1937, 426 of its 500 boats were mechanized. The port is sheltered by the natural breakwaters of the Pointe du Leide and He Tristan, and consists of three parts: on the west is the small fishing port of Treboul almost enclosed by He Tristan, on the ria estuary of Pouldavid is the commercial harbour of Port-Rhu; which supplies the fishing fleet with coal, wine, bait, food, salt, etc.; while the real fishing harbour is in the extremely busy Grand-Port, with its sardine factories and railway sidings. Douarnenez is probably the most prosperous fishing port in France, as it has three distinct fishing flotillas—250 sardine boats, eighty large tunny boats and thirty lobster boats, and in addition to these

some hundreds of boats are engaged in the coastal fisheries. There are twenty-four fish-preserving factories, most of them with modern equipment; women supply the labour, which is specialized and well paid, but intermittent.

Concarneau (Plate 42). This provides a safe anchorage that can accommodate over 1,000 vessels. It also has twenty-four fish-preserving factories.

Lorient is very different from its neighbours; a modern port has been constructed to handle a large amount of fish. Until 1927, the *avant-port* was used by the fishing boats, but between 1920 and 1927 two docks for fishing boats were built by the state. These are the *Grande Bassin* and the *Bassin Long*, and now form the new fish port of Keroman. Dock gates are not necessary, and boats can get in and out at all tides. Colliers are able to berth on the outside of the quays, and adequate coal-storage accommodation with transporter belts enable twenty large trawlers a day to be refuelled. The prompt despatch of fish to market is facilitated by railway sidings and by services of express refrigerator cars. As a result, *Lorient* has become the second fishing port of France by weight of fish landed, although it is only third by value. Its boats take part in the tunny and sardine fisheries in the Bay of Biscay, in the mackerel and herring fisheries, and in the more distant deep-sea fisheries.

THE BAY OF BISCAY (SOUTH OF THE LOIRE)

The Biscay coast south of the Loire does not offer many natural harbours, and as a result sardine and tunny fishing is on a small scale and is distributed among numerous small villages along the coast.

Oysters. Ideal breeding grounds for oysters are provided by the lagoon coast of the Landes, by the Bassin d'Arcachon (Plate 44), and by the muddy estuaries between Marennes and Les Sables d'Olonne which are sheltered from the westerly gales by the islands of Oleron and Re. Along this coast the Portuguese oyster has largely superseded the European or plate oyster that is cultivated on the English coasts, although the latter has recently increased again in numbers, as shown by the following figures:

Millions of Oysters

	1911	1920	1926	1937
Portuguese oyster	790	378	1,084	1,230
European oyster	922	463	11	223

Plate 43. Le Croisic (Loire-Inferieure)

Le Croisic is typical of the numerous small fishing ports scattered along the coast. The harbour is situated on the southern shore of the Grand Trait, a large shallow bay.

Plate 44. Oyster pans at Arcachon

The young oysters are placed in these earthenware pans, which are sunk in the shallow lagoon (the Bassin d'Arcachon). It is thus easy to collect the oysters when they attain maturity.

Plate 45. The fishing port at Martigues

Along the Mediterranean coast of France are numerous small ports, sheltering little craft which fish the *etangs* and canals. This example is the St Sebastian Canal at Martigues a cul-de-sac used by fishing boats.

Plate 46. The fishing port at Marseilles

A large number of small fishing boats use the old harbour at the southern end of the port.

The oysters are collected from November to 1 May, and other fishing boats are often laid up during this time because oyster dredging is more profitable. The catch is made for 2 hr. before and after low tide, both men and women taking part, usually in punts. The oysters are cut off from the rocks upon which they grow in large clusters, or are dredged from shallow water. The small ones are sent to the culture beds (*parquets*) at Arcachon, Marennes, Oleron, etc., and the large ones are packed in barrels to send to the Paris market.

Three ports, Les Sables d'Olonne, Marennes, and Arcachon, have over 1,000 registered boats; but most of these are small, and include many oyster punts. *La Rochelle* is the second French fish port by value and fourth by weight of catch. The outer basin of La Rochelle has a fish quay 400 m. long used by a fleet of eighty large steam trawlers, while the smaller fishing boats use the stranding basin. Alongside the fish quay are extensive fish sheds and railway sidings. The neighbouring port of La Pallice accommodates twelve of the largest trawlers, which go to the Newfoundland and south-west Greenland Banks. Smaller trawlers fish for hake, mackerel, herring, etc., while there are extensive coastal fisheries with Diesel and petrol-driven boats, catching turbot, sole, tunny, crab and lobster.

Bordeaux owed much in earlier days to the import of dried cod, and although a large amount (valued at 66 million francs in 1937) is still landed, the item is relatively of small account among the multifarious activities of the great colonial port. There are no special fish docks.

THE MEDITERRANEAN COAST

The fisheries of this coast are much less important than those of the rest of France, but over 9,000 men obtained employment in 1937.

Miscellaneous fishing. The Rhone delta has a large number of little fishing villages. Red tunny, sardines, anchovies, *poisson bleu*, mackerel and skate are caught in the open sea, and a variety of less well-known fish are caught in the lagoons and waterways. The red tunny, much bigger than its Atlantic relative, appears in shoals at the beginning of summer off the coasts of Sicily, Sardinia and southern France. Only 1,800 metric tons of these fish, about a fifth of the total of white tunny, were landed in 1937. It is caught by *madraques*, enormous wide-meshed vertical nets up to 300 m. long, or by *seinches*, a series of nets laid by a number of vessels round and

below a shoal, or by harpoons. The oyster beds at Thau, nearly wiped out by too thorough dragging in 1,907, are carefully conserved.

Some of the fishing methods on this coast are very different from those in other parts of France. The Sete fishers have long boats coupled in pairs (*bateaux boeufs*) behind which they drag a long net with wide wings, an effective method of catching such pelagic fish as sardines and anchovies. Single Catalan boats, or *palavas*, lay drift nets in summer in the open sea, while at all seasons the individual fisherman and his family work in the *etangs*, catching fish by harpoon or by series of complicated fixed nets (*esturies*, *triangles*, and *trabaques*). Nomadic fishermen camp in summer on the coast between Sète and Agde for the special seasonal fishing. People from towns outside the delta, and even from Italy, come every summer to Thau for the shell-fisheries, working until they leave for the wine harvest in Languedoc and the Rhone Valley.

The two most notable of the Mediterranean ports of France are Marseilles and Toulon. There is no special provision, however, for the fishing industry at *Marseilles*, and only about 4,000 tons of fish were landed in 1937—a very small part of the trade of that great port. The 700 registered fishing vessels are mainly small craft of about 2 tons which share the Outer Port with pleasure craft (Plate 46). Although *Toulon* has over 800 small craft, it landed barely 1,000 tons in 1937. *Site*, situated to the west of the Rhone delta, has more boats than any other fishing port in France, but they average less than 3 metric tons each.

ORGANIZATION AND RESEARCH

The government department responsible for the administration of the fishing industry, for the registration of boats, fishermen and catch, and for the compilation and publication of statistics, is the *Ministre de la Marine Marchande*. Scientific aspects of the industry are controlled by the *Office Scientifique et Technique des Peches Maritimes*. Powerful local organizations, such as the *Societe du Port de Peche de Lorient*, superintend to a large extent the activities at the various ports.

Research is carried on at over twenty marine biological stations round the coast. The *Office Scientifique* maintains a laboratory at Paris and at St Servan, a large *Laboratoire de Biologie appliquee a la Peche* at La Rochelle, and numerous smaller stations at many of the ports. Special interest is taken in oyster culture; the *Office Scientifique* maintains the *Inspection Generale du Controle Sanitaire Ostreicole* at

Paris, and there are research stations at Auray, La Rochelle, La Tremblade and Arcachon. Other marine biological laboratories are maintained by (1) the *Ministere de l'Education Nationale* at Wimereux, Luc-sur-Mer, Dinard, Biarritz, etc., (2) by the universities, notably the one maintained by the Sorbonne at Roscoff, and (3) by various public and private societies and institutions. An example of the last is the famous *Institut Oceanographique*, maintained by the Principality of Monaco. France assists international fishery research through her membership of the *Conseil Permanent International pour l'exploration de la Mer* at Charlottenlund in Denmark.

BIBLIOGRAPHICAL NOTE

(1) Detailed statistics are given in the annual official publication, *Statistique Annuelle des Peches Maritimes*, edited and published by the 'Ministre de la Marine Marchande' (Paris). Summary and retrospective tables are given in the *Statistique Annuaire* (Paris). Summaries are also conveniently given in the *Bulletin Statistique des Peches Maritimes des pays du nord et de l'ouest de l'Europe* (Copenhagen), published annually by 'Le Conseil Permanent International pour l'exploration de la Mer'.

(2) The 'Office Scientifique et Technique des Peches Maritimes' publishes the quarterly *Revue des Travaux de l'Office des Peches Maritimes*, which contains valuable articles on many aspects of the fishing and allied industries. It also publishes periodically numerous *Notes et Rapports*, and also a series of *Memoirs* which consist of statistical surveys, summaries of recent research, etc.

Chapter V

MINING AND INDUSTRY

Introduction: Industrial Regions: Coal: Iron Mining and the Iron and Steel Industry: Shipbuilding: Locomotives: Aircraft: Non-ferrous Metals: Electricity: Chemical and Allied Industries: Textiles: Miscellaneous Industries: The Vichy Regime: Bibliographical Note

INTRODUCTION

The first steam engine in France was erected at Le Creusot in 1790, and it was only in the last decade of the eighteenth century that France began to emerge from an elementary stage of industrialization. The state had turned its attention to the fostering of industry and was encouraging the Leblanc process of manufacturing soda; beet-sugar refining industries were set going, new sources of saltpetre had been found, and bleaching by the use of chlorine had been developed. In addition, schools of engineering and industrial science had been set up. The stage was set, but although during the following half-century most of the industries of France were remodelled, there was no spectacular change such as was witnessed in England and later in Germany. Progress was almost imperceptible. St Etienne and Roubaix were the only two towns that increased in size with any rapidity during that period. The two main brakes on the spread of mechanization were cheapness of labour and lack of coal. The oldest colliery in the northern field, that of Anzin, was not opened before 1720, the steam pump was not introduced until 1734, and there was no serious exploitation of coal till 1850. True, the output had doubled between 1828 and 1847, but production in the latter year was only about 5 million tons, whilst consumption about that time, though greater, was only 7½ millions.

In the iron and steel industry, the works on the edges of the Central Massif—Le Creusot, Fourchambault, Montluçon and Decazeville—were still the most important, and as late as 1846, three-fifths of the iron smelting was still carried on in small and primitive charcoal furnaces. Of steam engines there were fewer than a score in use in 1815, and even by 1850 only 5,200 were in use as against 22,500 water mills of various kinds. Even in the textile industry, which developed far more quickly, there were two water mills for every steam mill as

late as 1848. Lille had started the first steam spinning mill in 1801. In 1803 the flying shuttle was introduced into Alsace. This was the pioneer area of modern French textiles, and it experienced something approaching an industrial revolution in the first half of the century.

The disaster of the Franco-Prussian war fell upon France before her heavy industries had been established upon a firm basis. The loss of the Lorraine ironfields with their nascent industries and of the well-established textile industries of Alsace was a great blow. Nevertheless, after 1872 France set out resolutely on the road to recovery. Road, rail and canal construction under state encouragement went on apace. The successful search for the continuation of the Lorraine ironfield on the French side of the new frontier gave to France a share in the advantage of the newly invented Gilchrist-Thomas process which enabled phosphoric ores to be used for steel making. Nevertheless, progress was not rapid.

It was only with the opening of the twentieth century that the forward movement began to be marked. Between 1900 and 1913 industrial activity increased greatly. Then came the war of 1914-18, which put a stop to normal progress, but stimulated invention. There followed a period of reconstruction during which the devastated areas were rebuilt and re-equipped. This gave an opportunity for the closing of small uneconomical units, for amalgamations, for the rebuilding of factories on modern lines with modern equipment, and for the development of housing schemes to accommodate miners and other workers.

The return of Alsace and Lorraine and the control for fifteen years of the Saar coal-mining territory meant, for France, not only the possession of the largest and most easily worked ironfields of Europe, but the acquisition of a highly equipped, modern heavy metallurgical industry, as well as an important and specialized group of textile manufactures. France saw her industrial potentialities vastly improved, and the stimulus of a new orientation was beneficial to her status as a manufacturing country. Many difficulties were, of course, consequent upon this reorientation, not the least being the problem of finding new markets; for the German market organization, except for certain international iron and steel firms, was not acquired with the restored territory. Moreover, welcome as the additional coal supply of the Saar might be, without the access to Ruhr coal in exchange for iron, which the Germans had organized, France was still heavily handicapped by lack of metallurgical coke and by difficulties of communication between Lorraine and the **northern**

coalfields. In fact, Germany lost more than France gained by the separation of Lorraine from the Ruhr.

The period of reconstruction, absorption and re-orientation during which France consolidated her position among the great manufacturing countries of the world, lasted until 1929, when the world economic depression set in. In this crisis, the well-balanced position of the country between large-scale and small-scale industries and the weight of her still important and almost self-sufficing agricultural activities saved France from catastrophe.

By 1936 recovery became marked, but not in time to stem the constantly recurring labour unrest, manifested by repeated strikes; nor to avert the attempt at conciliation by the granting of a 40 hr. week, the result of which was a distinct decline in industrial production. Rearmament, however, set the wheels of industry revolving again with a rapidly increasing tempo. This acceleration continued until the collapse of May 1940.

In all this story of spasmodic industrial development, France has lagged far behind her neighbours. This slow progress is best explained by a consideration of the most outstanding characteristic of French industrial activity—the persistence of a *petit-bourgeois* attitude among the organizers and of the peasant attitude among the workers of France. The preservation and adaptation of the individual skill of the peasant craftsman displayed in small factory and cottage industries and the canalization of this specialized but cheap labour in the service of large markets, has been the outstanding feature of the great French luxury industries; and although it has called for a high degree of intelligent organization and co-operation, it has militated against concentration. This has been particularly marked in the textile activities of the Lyons area and indeed in the bulk of French industry, other than that which is concentrated on the coal- and ironfields. Yet it is in the nature of things that this loosely knit but highly efficient method of production should eventually give way to concentration of effort and mass production, as competition becomes fiercer and improved communications encourage and facilitate migration of the worker to the larger towns.

To sum up: The peripheral situation of the major iron- and coal-fields of the country and the inadequate supplies of coal and metallurgical coke have resulted in a slow pace of industrialization, in the continued quasi-self-sufficiency of French agriculture, and in the survival of many small-scale but highly specialized industries to supply the world's luxury markets.

As an index of the relative importance of the various industrial occupations in France, the following table is appended, giving the number of people employed in each of the main branches of industry; for comparative purposes and for completeness the non-industrial occupations are also included.

Industrial and other Occupations in France', 1931

Occupation	No. of persons employed	Occupation	No. of persons employed
Fishing	66,747	Textiles:	920,460
Forestry	58,447	Cotton, spinning and weaving	192,036
Agriculture	7,578,986	Wool, spinning and weaving	167,467
Mining	366,948	Silk	123,085
Quarrying	73,729	Hosiery	120,199
Food industries	541,671	Lace	90,224
Chemicals	238,297	Linen, hemp, jute	99,987
Rubber	63,124	Bleaching and dyeing	67,681
Paper and cardboard	103,281	Clothing	1,001,136
Printing, etc.	154,819	Leather, shoes, gloves	299,923
Ferrous metallurgy	147,034	Wood-working	649,270
Non-ferrous metallurgy	26,197	Transport	811,298
Engineering:	1,436,612	General commerce	2,329,219
Forging, edge-tools, wire	06,441	Banking, insurance	288,983
Mechanical engineering	80,131	Professions	657,757
Electrical engineering	50,409	Domestic and personal service	893,376
Building construction, etc	886,138	Public services	1,313,415
Cement, bricks, pottery, glass	223,095	Total occupied population	21,611,835

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

INDUSTRIAL REGIONS

Figs. 63 and 64 show respectively by departments the percentage of the working population engaged in industry and the amount of steam power employed in driving machinery. Viewed in conjunction with Figs. 70, 83 and 81, showing iron and steel production, number of textile workers and consumption of electricity in chemical and metallurgical industries, these maps provide a broadly accurate picture of the distribution and relative importance of the major industries of France. Five dominant industrial areas stand out: (1) the northern region, comprising the two departments of Nord and Pas-de-Calais; (2) the eastern region, including Lorraine and Alsace; (3) the region of the Centre, whose boundaries are less well defined, but whose nucleus lies in the departments of Rhone and Loire. This area sends tentacles into the northern Alps (Grenoble area) and into the southern Jura;

(4) the region of the Garonne basin, including the Pyrenees, with control centres in Toulouse and Bordeaux. This is defined in Fig. 81, showing electrical energy consumed in chemical and metallurgical work; (5) the metropolitan area of Paris, the industrial importance of which is indicated by a remarkably high consumption of steam power in factories.

Fig. 63. Percentage of working population engaged in industry, by departments, 1936

Based on *Recensement general*, 1936, vol. 1 (Paris, 1938).

Apart from these main industrial regions there are very many isolated industrial towns such as Troyes and Reims carrying on specialized work of considerable importance—survivals of provincial independence.

The northern region is paramount, the main locating factor being, of course, the coalfield. The two departments of Nord and Pas-de-Calais produced, in 1938, 28 out of the 46 million tons of coal mined in France, 1 million out of the 8 million tons of pig-iron, and 1½ out of the 5 million tons of steel. Furthermore, the region is one of the chief textile centres, having 2·8 out of the 8 million, ordinary cotton

spindles of France and employing some 200,000 textile workers in the department of Nord alone.

The industrialization of the *eastern region* is based for the most part, not on local coal, although the Saar basin has had some influence on its development, but on the presence of the important

Fig. 64. Steam power in industry, 1936, by departments

Based on *Annuaire Statistique*, 1938, pp. 109-10 (Paris, 1939).

Squares proportional in area to developed power. In some areas (e.g. Paris, Lorraine, Pas-de-Calais and Le Creusot), where there are many very large power-producing plants, the average power of the individual prime mover (i.e. steam engine) is high; in other districts (e.g. lower Seine, Nord, St Etienne), where there are numerous small-powered engines driving the machinery of small textile or light engineering factories, the average power is much lower.

minette iron ores of Lorraine. The output of ore in 1913 amounted to about 43 million tons; after the war of 1914-18 it rose to a maximum in 1929 of over 50 million. The ore from this field constitutes roughly 90 % of the national production. About half the output is consumed in the iron and steel industries. This region

employs as many iron and steel workers as the north, but is concerned mainly with the production of pig-iron, of which its output in 1937 was 6'2 million tons, as compared with only 1 million in the north. The textile industry of the east was based on the water power, soft-water supplies and skilled domestic textile labour available in the valleys on the flanks of the Vosges—the eastern valleys in Alsace, the southern valleys in the Belfort district, and the western valleys in Lorraine. The area includes also the slopes of the northern Jura. The industries of these groups of valleys have between them 5 million cotton spindles and employ some 116,000 workers in the textile industry with all its branches.

The metallurgical industries of the *Centre* are based on the small coalfields of the eastern Central Massif, but they also rely, to a certain extent, upon coal imported into the district, and wholly on ore and metal from other areas. The district only employs one-fourteenth of the labour devoted to metallurgy in France, but is important because it includes the principal armaments works of the country, at Le Creusot and St Etienne. The engineering industry is, to a certain extent, centralized in Lyons, but light metallurgical work, dependent on the electric furnace, is located in the Alps and the Central Massif. The centre of textile manufacture is Lyons, but the industry occurs over a wide area—in the eastern uplands of the Central Massif, in the southern Jura, and in the northern Alps as well as in the Rhone valley. In 1931 the silk and rayon industry employed about 123,000 persons. Power is obtained from the small coalfields of the region, and, to an increasing extent, in the form of electric current generated from the torrents of the Alps, the Jura and the Central Massif. The raw material for the silk industry is now for the most part imported from the Far East via Marseilles. Smaller quantities come from Syria and Italy.

A south-eastern sub-region centres in Grenoble. Here again, modern development is clearly allied to the exploitation of hydro-electric power. Powerful glacier-fed torrents and glaciated valleys with abrupt breaks of slope are the geographical conditions underlying this development. Conditions favouring the generation of hydro-electricity are not conducive to accessibility and ease of communications. Hence raw materials must be light. On the other hand, the electric furnace is necessary for the production of aluminium and of certain types of steel and ferro-alloys and for electro-chemical work. The majority of French aluminium works are situated in the Alpine valleys, Small-scale industry, thanks to electric power and a

certain amount of state encouragement, has penetrated into the heart of the Alps, in the upper valleys of Isere and Arc, but the more important industrial groups are found in the broad vale of Gressivaudan that lies between Grenoble and Chambery. Glove factories, cement works, engineering shops, silk and rayon factories line the edges of the plain. There are no less than 357 silk-weaving establishments in the department of Isere alone. Thus the industrial sub-area of Grenoble overlaps, to a considerable extent, that around Lyons.

The south-west, or Pyrenean region, looks mainly towards Toulouse, but has a western focus in Bordeaux. As in the Alps, economic development has accompanied the utilization for electric power of the mountain torrents. Apart from a little mining of iron and silver-lead-zinc ores and of some of the rare metals, activities are concerned with electro-metallurgical and electro-chemical work. Electrical energy is also supplied to Toulouse, where an important nitrate plant has been established. Though the Pyrenean industrial activities come a very long way behind those of Lyons and Grenoble, the two regions have much in common. Power is supplied from the upper basins of the Adour, Ariege and Tet to the railways and industries. The quarrying of building stone and of limestone for cement, the mining and reduction of bauxite, iron mining and a little steel production are the chief of the mountain industrial activities. In Bordeaux and Toulouse there are leather and skin industries; whilst the manufacture of superphosphates, of explosives and recently of aeroplanes has reached some importance.

Greater Paris is the largest manufacturing region in France, its population of 6 millions providing both a reservoir of labour and a market. The luxury industries, with which it is popularly associated—such as fashion goods, fabrics, jewellery and glass-ware, *objets d'art*, etc.—are of relatively minor importance. Besides these and the usual 'metropolitan' industries—printing, food production, textiles, furniture-making, public works contracting—many others are highly developed, especially the metal-using industries. All the important motor-car factories of France, save one, are found here, many of the aircraft factories, and electrical and light metal industries in great variety (see Fig. 35). The heavy industries, moreover, are also considerable: St Denis is one of the two most important centres in France for marine engineering, and the construction of heavy electrical equipment, factory machinery, barges and small craft, together with the manufacture and repair of rolling stock, all have important centres in the region (see Fig. 36).

Electric power is derived mainly from hydro-electric generating plants in the Central Massif, but the Paris region has six large thermal-electric stations (see Fig. 78) which supplement the current output as and when required. Large quantities of coal are consumed by individual factories, and the gas works also play an important part in industry. In 1936 the department of Seine produced nearly 650 million cu.m. of gas—40% of the entire French production—and nearly 700,000 tons of gas coke. The power stations and gas works, like the heavier industries, lie mainly downstream at St Ouen and beyond Gennevilliers in the river loop, and upstream at Ivry and Vitry, with minor groups in the central section of the river around Issy, so as to secure adequate supplies of water, cheap water transport for coal imports, and ample building space in the low ground of the river flood-plain, which is in any case less desirable for residential sites.

While the best known products of Parisian industry are made in small workshops, the bulk of the industrial output comes from larger establishments; the distribution of the factories is shown in Fig. 34. They lie in a belt of varying width which almost encircles the nineteenth-century city except where the Bois de Boulogne, to the west, forms a non-industrial gap. As far as transport facilities are concerned, the river, railways and roads seem to have offered more attractive locations for industry than the canals, except along the northern end of the St Denis Canal. The heaviest metal industries lie near the river at St Denis, Gennevilliers and farther downstream, though there is a subsidiary centre above the Marne confluence, and an important centre at Corneuve and Le Bourget, along the Nord railway leading to Laon. The electrical, motor-car and aircraft industries, the latest to develop, have a pronounced westward location towards the river at Suresnes and Courbevoie with an isolated group in the south-west bend of the great loop at Boulogne-Billancourt. In the earlier development of factories, within the limits of the fortifications, the general metal industries concentrated in the south-west and in the north-east, but in their later development in the suburbs they kept almost entirely to the north and north-east (cf. Figs. 35 and 36). The construction of ships, barges, dredgers, tugs, etc. has two centres—from St Denis downstream to Bezons, and upstream beyond the Marne confluence. Textiles have, in general, an eastward location; heavy chemicals are mainly concentrated at St Denis, but the manufacture of soap, photographic and pharmaceutical materials is fairly widespread; the tanning industry is concentrated along the Bievre river.

In the present century the greatest expansion has been westwards and downstream, with subsidiary movements to the north-east towards Le Bourget and south-eastwards beyond the Marne confluence. Recent years have seen a continuation of these tendencies with the establishment of the Ford factory at Poissy, just below the Oise confluence, and aircraft works at Colombes, Sartrouville and Les Mureaux. There has been expansion, too, in the district from Choisy to Villeneuve-St Georges above the Marne confluence, and along the main Orleans and P. L. M. railway lines. At Champagne-sur-Seine, for example, there is a new factory for the manufacture of electrical equipment covering 32 ha. In general, however, the expanding industry of the Paris region is attracted not south-eastwards towards the heart of the country, but north-westwards towards the lower Seine, the ports of Havre and Rouen, and the canals leading to the northern coalfield.

COAL

France has always been deficient in coal. The average production for the years 1932-8 was about 46 million tons, whilst the average consumption for the same period was 71 million tons. The following tables give some details of production and consumption.

The Northern Coalfield

France has only one large coalfield. It lies in the departments of Nord and Pas-de-Calais, and is a continuation of the Belgian field that skirts the northern edge of the Ardennes. The French part of the field is worked in a long curving belt at the foot of the chalk ridge of Artois from the neighbourhood of Aire to the Belgian

	Rhône	1'33	

frontier (Fig. 66). The coal lies beneath a hidden upfold of chalk overlain by soft, sandy deposits which rise slightly above the Flanders plain to form the Pevele and Gohelle districts. The deep-seated strata have been greatly disturbed by faulting and overthrusting and the coal measures have been folded over upon themselves in the southern part of the basin, so that they lie, in places, beneath sedimentary rocks of an earlier age. The coal zone is divided by faults into a series of sub-basins, besides which faulting has frequently interrupted and displaced the seams. This makes mining difficult and expensive. The French part of the coalfield covers about 51,000 ha. and forms a narrow belt about 100 km. long and 5-15 km. wide. From the Belgian frontier it passes west-south-west through Valenciennes towards Douai and then turns west-north-west through Lens and Bruay. It ceases to be worked beyond Ftechinelle, just south of Aire, but its presence has been proved in the Boulonnais, suggesting a continuation of the deposits in the direction of Kent.

Fig. 65. Above: distribution of coal and lignite fields, with 1936 production figures. Below: output in 1936 by departments
Based on *Statistique de L'Industrie Mine'rale*, 1936 (Paris, 1938).

There are many thin seams, some of them less than 0.4 m. thick, the average being about 1 m., and mining is carried on at depths exceeding 900 m., the average being 400 m. In parts of the Nord department the seams dip at an angle of 40° . Mining is easier in the Courrières-Lens-Grenay district of Pas-de-Calais, where the strata

Fig. 66. The northern coalfield. Above: distribution of collieries in relation to navigable waterways. Below: distribution of coke ovens, iron, steel and engineering industries in relation to railways (see also Plates 47, 48 and Fig. 73)

Based on the *Carte Industrielle* and the 1 : 25,000 maps forming G.S.G.S. series 4041.

dip less steeply and where there are some thick seams. Intervening barren rocks divide the field into two sections—that of Valenciennes in the east and that of Lens in the west. The quality and type of coal varies greatly in different parts of the field and even in the same district (cf. table on p. 180). For example, at Aniche coal of highly volatile composition occurs in the upper seams while **hard** anthracite is **mined at greater** depths.

During the war of 1914-18 the mining area suffered great damage by shelling and through the flooding of the mines by the Germans in 1915-16. In the 10 years succeeding the war the district was restored, the mines re-equipped on modern lines and their productive capacity improved. Since then mining methods have continued to make progress. The amount broken down with the pneumatic pick-hammer in Pas-de-Calais increased from 86.3% of the output in 1929 to 92% in 1936. In 1913 the percentage had been only 47. In the Nord department mechanical extraction reached 99.1% in 1936, but dropped to 97.8% in 1937. Between 6,000 and 9,000 pneumatic drills are used, and there are over 1,500 km. of pipes to carry compressed air to the coal faces. Coal mining is in the hands of a dozen large firms and several smaller ones. Eight of the large companies have an annual output of between 2 and 4 million tons each.

The making of *metallurgical coke* (Figs. 66, 67) takes place at many points on the coalfield, particularly in the Lens (Pas-de-Calais) section, which has about 1,500 out of a total of 2,500 coke ovens. In this western part, almost all the coke output is from local coal, but in the east there are a number of large installations, set up for the most part since 1918, which use in addition Belgian, German and Dutch coal. About one-half of the French output of metallurgical coke (which amounts to about 5 million tons a year) is made in the pithead cokeries of the northern coalfield, the location of which is indicated on Fig. 66. The output of gas from these cokeries in 1936 amounted to 1,327 million cu.m., most of which was used directly in the mining, metallurgical and chemical industries or for the generation of electricity. Apart from gas, the chemical by-products of coking have been rapidly increasing in importance, and now far outweigh in value the gas and coke produced (see below, p. 224).

In comparison with that of metallurgical coke and gas produced from coke ovens, the output of coal-gas and gas-coke from retorts at gas works is small—only 42,000 tons of coke and 35 million cu.m. of gas in 1936. A gas grid, similar to those of Belgium and the Ruhr, for the pooling and distribution of coke-oven gas and coal-gas, has been established. It covers a large part of northern France, the main centres being Bethune, Douai, Lille and Valenciennes.

The manufacture of *patent fuels* affords an economic means of using up coal dust and waste, which is mixed with pitch derived from tar distillation, or imported. It is carried on at Aniche, Ostricourt, Anzin, Bruay, Nœux-les-Mines (see Plate 47) and Courrières. Briquette making (10 kg. blocks of fuel used on railways and ships)

Plate 47. Coal mining at Noeux (Pas-de-Calais)

The installation comprises the pit-head, shale-heaps, a briquette factory and extensive railway sidings, in a setting of cultivated fields.

Plate 48. Iron and steel works at Escaudin (Nord)

This modern works lies just west of Denain (see Fig. 66). In the centre is a group of four blast furnaces; to the right, steelworks and gas-holder; in the distance, beyond a stretch of arable fields, a 'garden city' on the outskirts of the old village.

Plate 49. Coal mine at Mericourt (Pas-de-Calais)

A comparatively small mine (compare Plate 47), but none the less typical, with pithead gear, dumps of pit-props, railway sidings and a modern workers' village of houses with gardens—known in this case as 'cité du Maroc.' The mine lies about 4 km. south-east of Lens.

Plate 50. 'Cites ouvrières' near Lens

A 'garden city' built for miners by a colliery company—a considerable advance on the crowded urban industrialism of the nineteenth century.

and the making of 'ovoids' for domestic stoves have attained considerable importance. Nearly three-quarters of France's patent fuel production, which amounts to 8 million tons, comes from works attached to coal mines, and of this, in 1936, 57.5 % (nearly 37 million tons) came from the northern coalfield. Aniche produced the bulk of the briquettes.

Fig. 67. Output of coke by departments, 1936

Based on *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

Squares proportional in area to output. In general, metallurgical coke, i.e. for use in blast furnaces and in certain other operations in iron and steel manufacture, is produced in batteries of ovens, either at the pithead in coal-mining areas or adjacent to smelting works. Gas coke, used domestically and in factories for heating and the raising of steam, is a by-product of the manufacture in retorts of ordinary coal-gas by gas works. Metallurgical coke is much harder and less frangible than gas coke: it has to withstand the heavy burden of ore in the blast furnace.

In the modernized collieries of this coalfield the output is now used to the utmost: new methods of washing and screening ensure

the maintenance of an even grading of the coal and the efficient collection of dust, whilst patent fuel making, coking, the making of tar products and finally the hydrogenation of coal to produce fuel oil are ancillary industries (see pp. 224-5). The reconstruction of the devastated coalfield area after 1918 made possible a great improvement in the housing of the mine workers, and the older, rather drab rows of gardenless cottages ('corons') have given way to 'cites' or 'garden villages' of separate houses, each with its own garden, laid out in rectangular or other geometrical patterns (see Fig. 73 and Plates 49 and 50).

The Eastern Coalfield

The Saar coalfield, handed back to Germany in March 1935, extends beneath the frontier into the French department of Moselle in Lorraine (see Fig. 71). Coal is mined in the valley of the Rosselle, a left-bank tributary of the Saar, and in the small valleys of the Merle and the Bisten. Farther west the coal measures lie too deep for exploitation, but faulting brings them to within 790 m. of the surface at Pont-i-Mousson on the Moselle. It is not yet mined here, but its presence beneath the iron ores of the district may one day be an important factor in the development of the Lorraine iron industry. Modern improvements in the technique of deep mining, however, have made possible a small westward extension of the Lorraine field. During the 15 years in which France controlled the Saar mining interests, this Moselle section of the field was vigorously exploited: the Germans even accused the French of extending their galleries across the frontier into Saar territory. Be that as it may, output of coal in Moselle increased from 379 million tons in 1913 to 67 million tons in 1938, and has provided a valuable contribution since 1935 to France's depleted resources. The quality of the seams improves on the whole with increasing depth. The Petite-Rosselle mines have a seam 3'4 m. thick and produce coal of good quality. The La Houve mines give only poor-quality coal, but this is utilized at the pithead for the generation of electric current. The deep mines of Hopital and Merlebach are worked by German iron and steel firms.

Saar coal, unfortunately, does not lend itself satisfactorily to the production of metallurgical coke without the admixture of other coal (cf. table on p. 180), so that the steel industries of the Saar territory depended largely on coal and coke imported from Westphalia. Nor is the utilization of coal for by-products very far advanced, but the use of small coal in the generation of electricity is important.

Coalfields of the Central Massif (Fig. 68)

The coal measures of the Central Massif are seamed with valleys following the original lines of folding and faulting, a condition which has greatly assisted mining and communications and therefore industrial development. Good examples are afforded by the line of depression that leads from the Rhone valley to the Loire along the St Etienne coalfield between Givors and Firminy, and that in which the Blanzky-Montceau-les-Mines mines occur in the Le Creusot district. This natural passage-way is followed by two main roads, a railway and the Centre Canal (cf. p. 205).

The Blanzky concessions employ about 9,000 workers and produce about 2 million tons of coal a year, as well as 300,000 tons of patent fuel. The Autun section of the Epinac field, a little farther north-west, produces in addition about 100,000 tons a year of oil shale, which is distilled locally.

The St Etienne field in the department of Loire had an output of 3-24 million tons in 1936 (Plate 51). Some of the coal makes good metallurgical coke, which is used locally (cf. p. 204). In 1936, 372,000 tons of coke were produced from 233 ovens at the collieries of St Etienne, Roche-la-Moliere and Firminy, together with the usual chemical by-products. Much of the rest of the coal is gas-coal, and gas is manufactured and distributed over a wide area. Some is used in the generating of electricity. The small anthracite field of Roanne is also in the department of Loire.

Farther south in Gard, at the foot of the Cevennes, the Ales coalfield with the mines of Grand-Combe and Barrage produce some 2 million tons of high-quality coal. About one-half of the output is used for the manufacture of patent fuel, in the production of which the department of Gard ranks second to that of Nord. The rest is mainly consumed by the local metallurgical industries.

From north to south, through the centre of the Massif, runs a line of faulting along which small coal basins are strung out. The Decize mines in Nièvre on the northern edge of the Massif encouraged the establishment of a small specialized steel industry, as also did those of Commentry. This last only produces half a million tons, but is useful to the industries of Montluçon. In Puy-de-Dôme the engineering and other industries of Clermont-Ferrand receive coal from the small basin of St Eloi, in the 'coal furrow', and Brioude and Brassac in a small upland basin in Haute-Loire also contribute small quantities.

Fig. 68. Coalfields and industrial centres of the Central Massif
 Coalfields stippled; chief railways are shown (double-track thick lines, single-track thin lines); the main hydro-electric power stations are indicated by crosses (cf. Fig. 78); R.G. Rive de Gier; S.C. St Chamond; F. Firminy. The industrial centres are referred to in the paragraphs on iron and steel and textiles (pp. 204-5, 236 and 239).

The two most important fields of the western part of the Massif lie in the river basins of the Lot and Tarn. The Aubin mines near Decazeville produce over half a million tons; they supply the armaments works of Tulle and the metallurgical works of Villefranche-de-Rouergue, Decazeville, and Viviez. The Carmaux-Albi collieries produce just under a million tons for the railways that focus in this district, for the steel works of St Juery and for the woollen industries and foundries of Castres and Mazamet. The Graissesac collieries have developed rapidly of late, and produced 200,000 tons in 1936.

Lignite

French lignite production is small compared with that of Germany, for example—less than 1 million tons as against about 180 millions—and its significance in the national economy is not great (Fig. 65).

Lignite Production, 1936

Region	Department	District	Thousand tons
Provence	Bouches-du-Rhone	Fuveaii	631
	Basses-Alpes	Manosque	79
South-west	Gironde	Hostens	198
Comtat	Gard	Barjac	21
	All other areas		14
		Total	943

There are small deposits in the Cretaceous and Tertiary rocks at numerous places in southern France, particularly in the departments of Herault, Gard and Landes, but the only two worked to any extent are those of Fuveau, north-east of Marseilles in Bouches-du-Rhone, and of Hostens in Gironde; in both cases the output is employed for the most part in the generation of electricity, but the Fuveau lignites are also employed in the production of alumina from the bauxite deposits of Var (cf. p. 213),

IRON MINING AND THE IRON AND STEEL INDUSTRY

The following comparative table illustrates the relative position of France in the coal, iron and steel industries of north-western Europe, the U.S.A., and the rest of the world.

Output of Coal, Iron Ore, Iron and Steel in 1936
{in millions of tons}

Country	Coal and lignite	Iron ore	Pig-iron	Steel
France	46'1	33'3	6'2	67
Great Britain	2285	12'7	7'7	11'8
Belgium	279		3'2	3'2
Luxembourg		49	2'0	2'0
Germany	319'7*	6'6	15'3	19'2
U.S.A.	488'8	486	31'0	47'8
Whole World	1,430-0†	1700	90'2	121'7

161 '3 lignite. † 200'0 lignite.

Four separate groups of industries are involved in what is commonly referred to as the 'Iron and Steel Industry', and the geographical influences on their location are worthy of separate analysis.

(1) The mining of iron ore is clearly' dependent on geological circumstances for its location, but the mode of utilization of the ore varies in accordance with its iron content and the nearness of the field to fuel supplies. Generally speaking a low-grade ore (iron content 20-30 %) will tend to be smelted on the spot because of the high cost of transporting bulky material only one-quarter or one-third of which is actually going to provide useful metal. A high-grade ore, on the other hand (iron content 50-70 %), may more economically be transported to a coalfield for smelting. Thus a large proportion of the lean Lorraine ore is smelted locally, whereas the richer Algerian ores are sent by sea to the ports of France and Britain.

(2) Blast furnaces for smelting iron ore may generally be found in one of three types of situation:

(a) At the source of the fuel, e.g. the northern coalfield and Le Creusot, especially if, as in these two cases, the industry is of long standing, and was based originally on small local ore supplies.

(b) On the ore field, e.g. Lorraine, using coal or coke imported from a distance.

(c) At ports, e.g. Boulogne, the lower Loire, and Boucau (Bayonne), where imported ore and fuel are both available.

(3) The steel-making industry has for its main raw materials iron, either molten or in pig form, and scrap; in 1936 the consumption of scrap was 27 million tons. The industry may therefore be located:

(a) Adjacent to a blast-furnace works, where molten iron from the furnaces can be converted directly, without loss of heat, into steel

(e.g. many works in Lorraine); this is the usual method in the great modern iron and steel works, where, too, the coal is coked on the spot, and power and by-products are derived from coke-oven and blast-furnace gases.

Fig. 69. Graphs showing output of coal, iron ore, pig-iron and steel, 1913, 1920-38

Based on *Annuaire Statistique*, 1938 (Paris 1939).

These graphs form a rough index of French industrial prosperity.

(b) In an engineering area where abundant scrap is available as a 'waste' product of the engineering works which at the same time form an assured local market for the steel output (e.g. St Etienne, the northern coalfield, and Paris).

(c) In an area where hydro-electric power is available for use in special small-capacity furnaces producing mainly high-grade alloy steels (e.g. in the Alpine valleys).

The process of steel making will also vary according to geographical circumstances. Thus an area far from coke supplies will tend to use the Bessemer converter, in which fuel consumption is almost nil, whilst the coalfield engineering regions will use the Siemens open-hearth furnace which uses fuel, but can take a large percentage of scrap. Further, since the bulk of the ores used, whether from Lorraine or Algeria, are phosphoric, basic linings to both converters and open hearths will be employed. So Lorraine makes what the French call 'Thomas' steel (basic Bessemer), the northern coalfield, St Etienne and most of the other centres make 'Martin' steel (basic open hearth). Crucible steel is mainly made in small quantities for special purposes, e.g. the making of armaments, cutlery, etc., and so the manufacture will tend to attach itself to the market for its products. Thus almost the entire French output—which only amounts to 4,000-5,000 tons annually—is made in the St Etienne area and at Le Creusot. Finally, as already mentioned, the regions with water power produce electric steel.

Iron and Steel Production by Variety, 1936 (in thousand tons)

Pig-iron		Steel	
Phosphoric (over 1 % phosphorus)	5,675	Acid Bessemer	39
Semi-phosphoric (0' 12-1-0 % phosphorus)	63	Basic Bessemer	4,410
Haematite	329	Acid open hearth	31
Special irons (Spiegel, ferro-manganese, etc)	163	Basic open hearth	1,918
		Crucible	5
		Electric	283
Total	6,230	Total	6,686

The relationship of the various processes and products of the iron and steel industries is illustrated in the annexed table.

(4) The working up of iron and steel into finished products is commonly termed engineering, though this in its widest sense embraces industries which use non-ferrous metals—copper, brass, zinc—as well as iron and steel, and many other diverse raw materials in addition. The location of specialized branches such as shipbuilding and marine engineering, locomotive building, automobile and aircraft manufacture is often traceable to definite geographical factors, whilst general engineering tends to be more ubiquitous in its distribution. Even so, the heavier branches tend to be located in areas where large fuel supplies for power are available, i.e. on the

OH (France HI)

IRON MINING AND THE IRON AND STEEL INDUSTRY

coalfields, where also generally speaking the main metallic raw materials are most easily obtained, whilst the lighter trades show a wider distribution corresponding mainly to the distribution of the major population centres which are their markets. Thus a map showing the location of all industries falling within the term 'engineering' would omit very few important towns in France (Fig. 74).

Iron Ore

Ores of iron are found in small quantities in the sedimentary rocks of most parts of France, and iron working and iron smelting have been carried on sporadically all over the country where wood was available for charcoal and water for the hammers. With the introduction of steam power, the main development of the industry took place on the northern coalfield, but a number of scattered industries survived on or near the small coalfields of the Central Massif, those of Le Creusot and St Etienne for example. To-day the local ores are either worked out or are unprofitable, but the industries based on them continue to exist by importing pig-iron and in some instances also coal. Some of the firms concerned are engaged in making armaments, and their survival, apart from industrial inertia, is due to an avoidance, for strategic reasons, of the frontier coal- and iron-fields. In other instances they have developed special interests, such as the making of crucible steel.

With the development after 1878 of the Gilchrist-Thomas process of steel making, the large-scale utilization of the phosphoric ores of Lorraine became the basis of the iron and steel industry of both France and Germany. The ore resources of France were doubled when she regained the Metz-Thionville portion of the ironfield after the war of 1914-18. The most recent estimate of the reserves puts the total at about 4,500 million tons, of which nearly 4,000 million tons lie in Lorraine, and almost all the remainder in Luxembourg. At the 1927 rate of extraction, it was estimated, exhaustion would be reached in from 60 to 100 years.

The annual production of the French iron mines has fluctuated greatly since the end of the 1914-18 war, in sympathy with the current political and economic situation (Fig. 69). In 1929, the peak year of post-war recovery, a total output of over 50 million tons was reached. The output dropped again, largely as a result of the world depression, but partly because Germany, the chief market for French ore, had turned increasingly to Sweden for supplies. The overwhelming preponderance of the Lorraine fields—Metz-Thionville in

From *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

the Moselle department, Briey, Longwy and Nancy in the department of Meurthe-et-Moselle—is clear from the above table; the last three have regularly contributed about 52% of the total national production, whilst the Metz-Thionville region (in German hands between 1871 and 1918) produced most of the rest (42%).

The only other ironfield of any note is that of Normandy. Though insignificant in comparison with that of Lorraine, it is remarkable for the richness of its ore. In 1929 and again in 1937 its output approached 2 million tons.

The Lorraine Metallurgical Industry

In Lorraine the ore underlies the oolitic limestone plateau of Jurassic rocks between the rivers Meuse and Moselle. The plateau forms a rough triangle, nearly 100 km. long from the Luxembourg frontier to its apex near Nancy and about 40 km. wide in the north. It has a scarped edge facing east and north-east; the ore outcrops along this edge and dips gently west or south-west. The iron deposits lie in the Aalenian series of rocks which are sandwiched between the lower layers of the Middle Jurassic and the upper layers of the Lias and are thus almost exactly equivalent in age to the Northamptonshire ores in Britain. The tributaries of the Moselle traverse the plateau from west to east, trenching deeply as they cross the scarped edge. In these valleys, and along the scarped edge of the plateau, the ore is exposed and can be reached by adits driven into the valley sides (Plate 52). On the northern edge of the plateau the iron beds can even be quarried in a few places. Farther to the west, they dip down and the valleys are not deeply etched, so that the ore is reached only by deep shaft mining.

The most important characteristic of the Lorraine ores is that they are phosphoric and therefore had to wait for the invention of the Gilchrist-Thomas 'basic' process in 1878 for their full exploitation. The upper beds of red, sandy ores are very friable, do not stand transport well and are largely used to mix with other ores; they yield up to 40% of metallic iron. Below these comes the best 'Minette' ore, unfortunately largely worked out. This occurs on the northern edge of the Briey plateau. A less rich, yellow, calcareous ore is found between the valleys of the Algringen and Orne. Below this again and much more widely distributed are grey, calcareous ores, having an iron content of only 38%, but occurring in relatively thick seams, varying from 2 to 6 m. Still deeper lie poor gravelly ores very little worked.

Fig. 70. Output of pig-iron and steel by departments, 1936
Based on *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

Although the ferruginous content of the Lorraine ores is not high, there are compensating factors that make the deposits very valuable. The dip of the strata is gentle and is very little disturbed by folding or faulting, so that mining is not costly, as it is, for example, with the rich Siegerland ores of Germany. The calcareous matrix makes the ores almost or quite self-fluxing, the siliceous ores of the Nancy region being an exception. Again, the Lorraine ores are porous and easily reduced, requiring a relatively small fuel consumption in

Fig. 71. Lorraine in relation to the coalfields and ports of north-western Europe. The main lines of rail and water transport are shown

smelting. The chief disability in the working of the ores is the relatively heavy cost of transport involved in bringing the ore to the fuel, or, conversely, the fuel to the ore. Communications are difficult in every direction (Fig. 71). The journey from the Westphalian coalfield is long and involves a steep ascent from the Rhine valley. Transport to the Franco-Belgian coalfield involves the crossing of the Ardennes. The Saar coalfield, which lies nearest, does not produce metallurgical coke without the addition of Westphalian or other coal. Furthermore, the field lies on the frontier between France

Plate 51. St Etienne

View of an industrial section of the town, with a large coal mine, showing pit-head gear, washing and election power station, and on the right a dump of pit-props; the whole is set on an undulating upland, just over 500 m. above sea level.

Plate 52. Iron mining in Lorraine

Entrance to an adit mine in the Fentsch valley near Hayange (see Fig. 72). The employment of electric haulage is general in the Lorraine mines.

Plate 53. Iron and steel works at Joeuf

The works are situated on a flat terrace in the deep-cut meandering valley of the Orne between Homecourt and Moyeuvre (Fig. 72); the river is in the foreground. In the centre is a group of blast furnaces with their attendant hot-blast stoves; to the right are steel works and rolling mills.

and three foreign countries, and disorganization has followed war three times within living memory.

The Lorraine field is divided by faults and barren ground into four producing areas: that of Nancy in the south, Metz-Thionville in the north-east, both lying near the scarped edge of the plateau of C6tes de Moselle, that of Briey in the broader western part of the plateau itself, and that of Longwy in the north-west, overlapping into Luxembourg.

The Nancy region was the first to be exploited. Mining by adits takes place in the plateau edges overlooking the Moselle and in those of the outlying limestone massif covered by the Bois de Faulx. The ores of this area are unsuited to long-distance transport, for they are sandy and friable and the iron content is relatively low. Moreover, the ore is not self-fluxing as in the other areas, so that limestone or calcareous ore has to be brought in to smelt it. Ore is exported from Maxeville, the port of Nancy, by way of the Marne-Rhine Canal to Burbach in the Saar Territory. Local smelting takes place near the mines along the Moselle valley, served by rail and water transport, at Maxeville, Frouard and Pompey, and farther south on the Canal de l'Est at Neuves-Maisons; there is an outlying centre in the north, not near any mines, at Pont-i-Mousson. There is a tendency for a greater development in the Nancy region than elsewhere in Lorraine of the manufacture of finished iron and steel products and of engineering, e.g. iron pipes at Pont-i-Mousson, electric locomotives and other electrical equipment at Nancy.

The Metz-Thionville region. North of Pompey mining ceases for 30 km. until the recently developed area of Noveant - Ars-sur-Moselle is reached. Beyond the latter, there is no mining in the immediate neighbourhood of Metz, but the ore field begins again west of Maizieres, 10 km. north of the fortress and continues along the scarp overlooking the Moselle valley to beyond Thionville. The bulk of the mining however is concentrated in the lower valleys of the Orne and Fentsch where adits penetrate the valley sides. The lower valleys of both streams are crowded with iron and steel works, coke ovens, miners' and metal-workers' villages (*cites*), roads and railway sidings. Much of the ore is moved by aerial rope-ways; some travels long distances in tunnels from valley to valley. In the Orne valley a long string of great works stretches from Auboue through Jceuf to Home-court, and again lower down at Moyeuivre and Rombas (Plate 53). In the Fentsch valley there is a similar line from Knutange through Hayange to Florange. There are also several large works in the

Moselle plain, alongside the main railway line—at Maizieres, Hagon-dange, Uckange and Thionville. Many of these works are highly integrated units, producing their own coke and using coke-oven and blast-furnace gases to generate electricity to drive the steel mills and to work the nearby mines.

Fig. 72. Industrial Lorraine. Left: iron mining in relation to navigable waterways. Right: the iron and steel industry in relation to railways

Based on the *Carte Industrielle de la Lorraine* (Paris, 1930).

The most noteworthy differences between these maps and those of the northern industrial region (Fig. 66) are the virtual absence in Lorraine of steel works unaccompanied by blast furnaces, and the presence of numerous blast-furnace works which have no attached steel works. This difference in the economy of the industry in the two areas is a result of their different relations to ore and fuel supplies and to the engineering industries (cf. p. 202).

The Briey region consists of the plateau to the west of the Metz-Thionville area. The self-fluxing ores of this area are mined in the upper basins of the Orne and Fentsch, and in the upper valleys of

the Crusnes basin which drains westward to the Meuse. Mining here is by shafts. Owing partly to difficulties of water supply and partly to those of transport, steel works have not developed on the plateau, and the ore is sent away to the Metz-Thionville district.

The Longwy region lies on the northern edge of the Briey plateau. The international boundary separating France from Belgium and Luxembourg passes along the escarpment on the face of which the ferruginous sandstone outcrops. Mining and metal working are carried on in the upper valleys of the Alzette and the Chiers. The mines are mainly worked by adits, but at Hussigny the ore is quarried in the open. Iron and steel works are crowded in the deep, narrow valleys along the railways. There are half a dozen, some of the most important in France, at the convergence of lines on Longwy-Bas in the Chiers valley, for the ores of this area are so sandy that they do not pay for transport and are smelted on the spot. A second group clusters around Villerupt in the upper Alzette valley.

External relations of Lorraine. Reorientation of the iron, as of the coal industry, of eastern France was greatly simplified by the international nature of the ownership and organization of the Lorraine industries, in which French, Belgian, Luxembourg and German interests were all represented. In spite of transport difficulties, which have always been a serious problem in the working of the ironfield, whether in German or French hands, and in spite also of the decline in the Ruhr-Lorraine interchange of coke and iron after 1918, the export of French ore and pig-iron was already recovering by 1929. In the years 1934-8 the export of pig-iron averaged 6 million tons. During the period 1928-33 Germany imported from France an annual average of 2 million tons of pig-iron, a figure which rose in the years 1934-8 to 6 millions. In the boom years of 1928-30, one-third of the French ore output was exported. From 1933 onwards exports rose owing to the decreased home demand, reaching 19*32 million tons in 1937. Belgium has always been the largest customer for Lorraine ores, taking an average in recent years of 10 million tons. Four-fifths of these imports into Belgium emanated from Belgian-owned mines in Lorraine.

The Northern Region

The iron and steel industry of northern France is based on the fuel supplies of the local coalfield, and is entirely dependent for raw material on ore and metal imported into the area. As a result, pig-iron is not produced in very large quantities—the average for 1932-8 was

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

J. H. GODFREY

Regional Variations in the Growth of Population: Introduction; Analysis of the Movements of Population; Rural Depopulation, Immigration of Foreigners

Rural Settlement: Main Types of Settlement; Geographical and Historical Factors in Settlement; Historical Development

Towns and Cities: Number and Distribution of Towns; Urban Growth; Conurbations

Note on Family Allowances

Bibliographical Note

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

(in thousands)

From P. Depoid, 'Structure Professionnelle', *Revue d'Economie Politique*, LVIII, 51 (Paris, 1939).

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture d'oree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loire (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

Fig. 5. The distribution of population in eastern France, 1931

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

Fig. 6. The distribution of population in south-western France, 1931

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

Fig. 9. The distribution of population in south-eastern France, 1931

Based on the *Atlas de France*, Plate 75 (Paris, n.d.).

A, Avignon; Ac, Annecy; Ae, Ales; An, Autun; Ar, Aries; Ax, Aix; Be, Briancon; Be, Beaune; Bg, Bourg; Bn, Besancon; Bo, Bourgoin; Cs, Cannes; Cb, Chambery; Ce, Le Creusot; Ci, La Ciotat; Cl, Chalon-sur-Saone; Cp, Carpentras; D, Dijon; Di, Digne; Do, D61e; Fr, Feurs; Fy, Firminy; G, Gray; Ga, Gap; Gc, La Grand Combe; Gr, Grenoble; Gv, Givors; L, Lyons; M, Marseilles; Me, Mentone; Mm, Montceau-les-Mines; Mn, Macon; Mo, Montbeliard; Mr, Montelimar; N, Nice; Nm, Nimes; P, Pontarlier; Ra, Roanne; Ro, Romans; StC, St Chamond; StE, St Etienne; T, Toulon; Va, Valence; Ve, Villeurbanne; Vn, Vienne; Vo, Voiron.

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	-35	546	176

* Including the Saar territory.

From (1) *Annuaire Statistique, 1938 (Resumi Retrospectif)*, pp. 11-13 (Paris, 1939); (2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	+ 4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2'0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938
0-4	8.2	6.8	8.1	9.5	10.3
5-9	8.4	7.2	7.2	9.6	10.9
10-14	8.6	7.8	8.0	9.5	11.4
15-19	5.6	8.1	7.8	9.2	9.7
20-24	7.3	7.9	6.9	8.5	7.0
25-29	8.0	8.4	9.1	8.3	9.7
30-34	8.0	8.2	8.9	7.7	8.7

65 +	9.8	8.5	7.6	6.7	
	100.0	100.0	100.0	100.0	100.0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	25.2	21.8	23.3	28.6	32.6
15-49	48.9	53.4	54.0	52.1	51.5
50 +	25.9	24.7	22.7	19.3	14.9
Women: 15-49	48.2	53.3	54.0	52.3	52.6

Of the total population men represent 48.3%; neglecting the foreigners in France, however, men represent only 47.3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations, 1938-9*, p. 44 (Geneva, 1939). For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

*Mortality by Age and Sex: Specific Rates per 10,000
Inhabitants of each Age Group*

Age	France 1935		France 1936		Germany 1936		England and Wales 1936		Netherlands 1936-37

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

		M.	F.
France:	1908-13	48.49	52.41
	1920-23	52.19	56.09

	1930-32	58.74	62.88

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 52-4 (Geneva, 1939).

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14·6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

	1932	1933	1934	1935	1936	1937	1938
Sweden	14'5	13'7	13'7	13'8	14'2	14'3	149
France	17'3	16'2	16'2	15'3	15'0	14'7	146
England and Wales	15'3	14'4	14'8	14'7	14'8	14'9	151
Belgium	17'7	16'6	16'0	15'4	15'2	15'3	156
Germany	15'1	14'7	18'0	19'0	19'0	18'8	197
Netherlands	22'0	20'8	20'7	20'2	20'2	19'8	206
Poland*	28'9	26'5	26'6	26'1	26'2	24'9	244

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0.880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1.0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1.0 for the greater part of this century:

Net Reproduction Rates

1908-13	0.930	1	1935	0.866
1920-23	0.977		1936	0.88
1925-27	0.929		1937	0.87
1928-33	0.905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Net Reproduction Rates

Poland:	1931-2	1.25	France:	1935	0.866
	1934	1.11		1937	0.87
Italy:	1931	1.209	Belgium:	1936	0.831
	1935-7	1.128	England and Wales:	1935	0.764
Netherlands	1930-1	1.28		1937	0.782
	1937	1.119	Sweden:	1935	0.729
Germany:	1931	0.748		1936	0.756
	1933	0.698			
	1935	0.906			
	1936	0.934			
	1938*	0.945			

* Official figure, arrived at by a method somewhat different from the method employed to determine the figures for the preceding years.

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141

Over 10,000 inhabitants 341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30 %, Toulouse 17 %, and Strasbourg 10 %; Nantes (6 %) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

***Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas***

Conurbation	Population in 000's	No. of com- munes included	Principal communes

29. C6te d'Azur from Cannes to Antibes	102	7	Cannes 49; Antibes 25; Vallauris 10

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

of paying family allowances encouraged the extension of the system to industry, and the shortage of labour in the years 1918-30 provided further incentive to employers to pay these allowances, in order to secure greater stability of labour by the employment of the largest possible number of married men with children. Another motive for the employers was a belief that allowances helped to withdraw family men from interest in the class struggle. To employees the scheme appeared as a means of raising their standard of living. In 1932, some 245 funds covering 1,850,000 employees, and distributing annually 380 million francs, were in operation, and affiliated to a central organization. As the number of private funds grew in these years, the rate of allowances paid to state, departmental and municipal employees increased. Eventually, in 1932, legislation was effected by which all employers were ultimately to subscribe to 'equalization' funds and to grant allowances for dependent children to all French and foreign wage earners and salaried employees.

In 1933 the number of beneficiaries amounted to 5 millions. The programme was extended to more industries, and in 1936 the system was made applicable to all industries and commercial undertakings employing more than ten people, including multiple branch concerns, while in the same year the law was extended to agriculture. The wide extension of the scheme is shown by the fact that the total payments in 1937 were 1,340 million francs, compared with 872 millions in 1936, and were estimated to reach 1,500 million francs for 1938.

Considerable variations were naturally to be found between different areas, both in the rates paid and the subscriptions levied on employers, owing to local differences in wage levels, cost of living, etc. The table on p. 79 illustrates certain rates.

When the scales were revised in 1938, it was provided that the minimum rates should be fixed by the Minister for Labour on the recommendations of the Higher Family Allowances Commission. The age to which allowances were payable for children, apprenticed or pursuing a course of studies, was raised to 17, but after November 1940, no allowance was to be payable for an only child over 5 years old. The new arrangement came into force in April 1939. ,

Machinery for Payment. Funds for the payment of family allowances are obtained entirely by subscriptions from employers. The charges amount to over 2% of the total wages bill in industry. Beginning in 1918, Equalisation Funds (*Caisses de Compensation*) came to be established as a means of regularizing the financial side. Employers contribute to the appropriate funds according to the

number of people they employ, and each fund then distributes the allowances. The Act of 1932 did not create any special machinery for the administration of family allowances, and the existing funds set up by employers were left untouched. Employers not already affiliated to equalization funds were obliged to subscribe. It is important to notice that in order to prevent employers from reducing their liabilities by employing unmarried staff, subscriptions to the funds (*caisses*) are payable for all workers, whether married or single. In 1938 a national compensation fund was established to make grants to local compensation funds, on which the charges were found to be abnormally high. The national fund, which is to be managed by the *Caisse des Depots et Consignations*, is to obtain its resources from subscriptions paid by all the local compensation funds. Until 1932 the subscriptions paid by employers were all voluntary.

Rates of Family Allowances, francs per month

	One child	Two children	Three children	Four children	Each ad- ditional child
1936: normal rate	30	70	120	200	80
1936: rate for state employees	52	76	157	196	—
1937: rate in Paris	30	80	200	400	200
1938: rate in Paris	60	160	300	500	200
1938: rates in agriculture	15 to 25	30 to 85	67'5 to 200	110 to 320	27'5 to 120
<i>Rates as percentages:</i>					
1938: rate in Paris as per- centage (approx.) of mean wage of 20 skilled trades	4	10	18	30	12
1939: minimum rate at re- vised scales for the whole of France, as percentage of adult male wage earner	5	15	30	45	15

Conclusion. It is probably too early to form a judgement upon the effectiveness of family allowances in retarding the decline of the birth-rate. The widespread application of the system has been in effect for too short a time to permit of statistically sound conclusions being drawn. As to the funds which were privately operated by firms on a considerable scale soon after 1920, such as the Michelin Company's fund for its employees at Clermont-Ferrand, it is held by some authorities that the higher birth-rate occurring among the beneficiaries of the funds represents inconclusive evidence. The employees are not a typical cross-section of the adult population as

a whole, and some of the employees may have migrated to the Michelin works so as to take advantage of the allowances.

While the payments under the schemes add to the income of parents, the addition is considerably less in amount than the increase in the cost of living incurred through-children. It has been estimated that three children add to the income of a lower grade civil servant an amount equal to only half of what they add to his cost of living. Hence it is considered by some that the scale of family allowances is too small to have any real effect upon the population position. At the most they may have resulted in a slight diminution of the rate of decline in the birth-rate. Such a view is only an opinion, and so far real knowledge cannot be arrived at until statistical investigation of the family allowance system has reached a much more advanced stage.

BIBLIOGRAPHICAL NOTE

(1) *The Census*

Vauban made an estimate of the number of inhabitants of France as long ago as 1700, and other estimates were made in 1762 and 1764. The first organized census was carried out in 1800, and in the next year, 1801, began the series of censuses, at intervals of five years, which has since been continued, except for the census of 1871, which was postponed for one year, and the census of 1916, which was not held.

When the census forms have been collected, they are first utilized to determine the figures of *population legale* in each commune, i.e. the numbers of persons having their habitual residence in the commune. The forms are then tabulated by the *Statistique Generale de la France*, and the entries analysed by category. The figures of *population presente* are obtained at this stage, i.e. the population actually present in each commune on the day of the census. In 1939 the later calculations had not been completed; only the figures of *population legale* or resident population have been published. These figures have been used in the foregoing account. The completion of the census was not expected until 1940. (See also p. 375.)

The published volume is *Resultats Statistiques du Recensement general de la population en 1936* (Statistique Generale, Paris, 1938).

Summarized statements appear in *Annuaire Statistique, 1938* (Paris, 1939).

Chapter II

PARIS

The Site: The Growth of the City: Inner Paris: Greater Paris: Bibliographical Note

THE SITE

The successive stages in the expansion of Paris from its nucleus on an island in the Seine are closely related to the physical features of its site, and are still clearly embodied in its plan. After receiving the waters of the Maine, the Seine, cutting through a line of low heights, begins the first of its loops towards the north. On the southern bank it receives a small tributary, the Bievre, which after flowing east and north is deflected eastwards again by a low spur, the Mont Ste-Genevieve (Fig. 27). In general the relief on the south bank is broken and of moderate elevation. This broken relief imposed limitations upon the city's early development to the south, but farther to the west near the Champ de Mars a portion of the flood plain allowed expansion. Off the Mont Ste-Genevieve, in the centre of the river, lay a number of small islands, now reduced to two—lie de la Cite and lie St Louis (Plate 10). These islands, and the numerous side branches which originally characterized this stretch of the river, due perhaps to the decrease in the slope of the bed, formed a complicated pattern, but it happened that a line from the southern height across the present lie de la Cite avoided most of the obstacles.

On the north bank, the relief is in contrast to that of the south. A semicircle of heights leaves the river at Charonne on the east, and runs through Menilmontant, Belleville, Montmartre, and Chaillot, returning to the river at Passy. These heights mark the northern slopes of the Quaternary course of the Seine, the loop of which was much more pronounced than that of the present river (Fig. 27). Probably owing to changes in the course of the Marne, which increased the velocity of the Seine, the latter cut off the extremity of this loop to occupy its present course. Thus the area immediately north of the Seine is a segment of a meander plain, originally sloping not to the Seine, which cut a narrow bed through it, but towards the older course. In the early history of the city this was occupied in its western portion by a stream flowing from Menilmontant, and in its eastern end by an area of marshland, Le Marais.

The north bank therefore afforded ample space for expansion, and the growth of Paris in this direction has been closely related to this abandoned river course. At one period, portions of it were incorporated as a moat forming part of the city's fortifications. At times, too, it has proved a source of anxiety to the city engineers, for the Seine in flood has occasionally attempted to reoccupy its former bed. Thus in the floods of 1910 subsoil penetration by this channel flooded large areas round the Gare St Lazare. The original relief, however, has been largely hidden by drainage, by newly-made ground, and by buildings. It is important to note also that the northern ring of heights is not continuous: Montmartre is isolated by gaps to east and west, the former being especially important as it affords an easy line of communication northwards.

The significant features of the site therefore are the approach of the southern hills to the river, the islands in the river bed reducing the difficulty of bridging, the open plain on the north bank, and the breeches in the northern heights. The three main areas—southern heights, islands, and northern plain—have persisted from early days as subdivisions with distinct characteristics associated respectively with Universite, Cite, and Ville.

THE GROWTH OF THE CITY

The Early Medieval City

Before the Roman occupation of Gaul, the Ile de la Cite was the site of a settlement, Lutetia, the centre of a Gaulish tribe, the Parisii. By this time the Seine had been bridged and the island was close to an intersection of routes, a south-to-north land route and an east-to-west river way. Roman observers remarked upon the busy boat traffic on the river. Under Roman administration the principal section of the town was laid out on the southern bank, on the slopes of the Mont Ste-Genevieve. A Roman road from Chartres ran northwards across the lie de la Cite and up through the Montmartre-Belleville gap; on the north bank it was joined by another road descending the valley westwards from Melun, and it was around this junction that commerce was increasingly to centre.

During the first centuries of the Middle Ages however progress was slow. In the disturbed times following the Roman withdrawal and the Frankish advance, when the Roman town on the south bank was destroyed, settlement was chiefly confined to the island with two bridgeheads north and south of the river. Under the Merovingians,

in the fifth and sixth centuries, order was re-established, and with the expanding influence of the Church the elements of civilized life gradually returned. During the reign of Clovis, the basilica of SS. Peter and Paul was built on the southern quarter, and other churches soon followed (St Benoit, St Severin). Settlement on the outskirts was encouraged by ecclesiastical foundations, the abbey of St Germain TAuxerrois on the north bank, and of St Germain des Pres on a former left bank island below the city limits. The surrounding forests were gradually cleared during the ninth century, and with the revival of trade the value of the position of Paris became recognized, by none more clearly than the early rulers of the House of Capet. Indeed, it was their great achievement to establish Paris as the undisputed capital of France. By their efforts the advance of the Norsemen was stayed at the city walls after a siege during which the southern quarter was again destroyed, and their royal duchy, extending north and south of the Seine and conveniently linked by Paris, was welded together to become the foundation of the kingdom of France.*

It was to the centralizing policy of the French monarchy more than to any combination of geographical factors that the city's predominance and extraordinary growth were due. As the seat of the central government, the courts of law, and the great university of the Middle Ages, Paris drew to itself, with increasing attractive power, first the professions and trades necessary to sustain their needs, and later an industrial population to meet the demand for goods as close to the market as possible. Thus the development of Paris has been from an administrative centre to a great commercial market, and finally to an industrial concentration. The development of a planned system of roads, of canals, and of railways merely tightened the hold of Paris on the country.

The effect of this Capetian centralizing policy was soon visible in the development of the city, which during the twelfth century assumed its characteristic tripartite form. The *lie de la Cite* was the centre of royal and ecclesiastical administration. In the middle of the century the building of the new cathedral of Notre Dame was begun, and the church schools formerly grouped around it moved across to the south bank where, around the theological college founded by Robert de Sorbon in 1253, the University and its quarter crystallized. Here gathered, besides masters and scholars, the attendant scribes, followed later by the printers.

On the north bank was the 'Ville,' the predominantly commercial

* For the historical background, see vol. 11, pp. 46 et seq., of this Handbook.

Plate 10. Paris: The He de la Cite

On the island is the Palais de Justice in the foreground, with Notre-Dame Cathedral and the Hotel Dieu near the other end. There is a clear contrast between the congested streets and buildings of the 'Quartier Latin' on the left bank (on right of picture), and the more elegant tree-lined avenues and open spaces of the right bank, where the Hotel de Ville is prominent.

Plate 11. Factories at Billancourt, Paris
The great Renault works extend over a large area and have even spread to the island in the Seine.

quarter; upstream from the bridges, along the creeks and quays, grew the first 'ports' of Paris. The importance of the river traffic, which carried down to the city the wines and timber of the upper Seine basin, is seen from the growing influence of the 'Corporation of water merchants', the head of which became during the thirteenth century the chief civil officer of the municipality. The principal 'port' was on the site now occupied by the Place du Chatelet, near the Hotel-de-Ville, and close to the *croisee de Paris*, the junction of the main routes. Between the water front and the roads were established large markets, an area still partly occupied by the Halles Centrales.

The City Walls

It was around this threefold area that Philip Augustus between 1180 and 1210 built the first city wall (Fig. 27). From the eastern limit of the trading quarter on the north bank it ran in a rough semicircle, the maximum distance from the river being about 800 m., to rest in the west on the recently built fortress of the Louvre. On the south bank it enclosed the Mont Ste-Genevieve, forming the limit of the city in this direction until well into the seventeenth century. The next period of growth was therefore on the north bank, at first eastwards until the marshland along the old course of the river was reached. This marsh was gradually drained and occupied by market gardens to supply the growing city, until it was built over in the eighteenth century. The second important line of fortifications, built by Charles V about 1370, began at the Bastille and incorporated the Louvre on the west. Within the old limits the population had been growing rapidly: on a basis of a census of hearths taken in 1329 it is estimated that the population was then about a quarter of a million, a remarkable figure for the period. The new walls, however, included considerable areas of open land sufficient for some time to absorb growth which at first slackened owing to disturbed political conditions, although by the seventeenth century the city was spreading rapidly beyond the walls, mainly northwards, despite successive royal edicts establishing forbidden zones. These were partly prompted by fears of inability to feed so large a concentration, hence the preservation of the gardens of Le Marais and the attention to the water supply. The city was dependent largely upon water from the Seine, pumped directly from the river at La Samaritaine and the Pont Notre Dame. In the middle of the fourteenth century the population was nearing half a million, a stage in its development which was not materially passed until the industrial era.

The next extension of boundaries had a fiscal rather than a military reason; to facilitate the collection of the *octroi* a wall, the 'Mur des Fermiers-Generaux', was built between 1784 and 1791, with a radius some 1,500 m. larger than that of the preceding wall. This carried the northern limits of the city to the line of the old river course and

Fig. 27. The site and growth of Paris

Based on G. R. Crone, 'The site and growth of Paris', *Geographical Journal*, vol. xcvi, p. 37 (London, 1941). For the work of Philip Augustus, see vol. 11, p. 49 of this Handbook.

the foot of the northern heights. It enclosed the faubourgs which had grown up along the radiating routes and much open land, especially on the south bank. Portions of the old ramparts became the line of the great or inner boulevards.

Throughout the eighteenth century the population did not rise above half a million, but with the progress of the industrial revolution the city again pressed upon its limits. By 1841 the inhabitants

numbered 935,000, and it was then decided for military reasons to fortify a much extended area. The *enceinte* was thrown along the northern heights beyond Belleville and Montmartre and southwards towards Gentilly and Issy. This brought within the limits of Paris a number of considerable towns, for Belleville had at that time a population of 57,000 people, and Montmartre 35,000. With the incorporation in 1861 of the communes thus enclosed, the population of Paris rose to 1,690,000. The wall of the Farmers-General then became the line of the outer boulevards.

Fig. 28. The built-up area in 1839

Based on *Carte des Environs de Paris*, drawn in 1839 at the Depot Generale de la Guerre, under the direction of Lieutenant-General B. Pelet.

Industrial Growth

With industrialization and improved communications, the activities of the population also began to change markedly. Formerly, the occupation of the Parisian workers, apart from the predominating official and commercial classes, had lain mainly in trades requiring traditional skill and taste rather than an abundant supply of raw material. With the building of canals and railways, supplies of materials

for heavier industries, particularly coal and iron, became available and industry was freed from its dependence upon the river front. In the twenties there was an epoch of canal building. The Canal St Denis and the Canal St Martin were followed a few years later by the Canal de l'Ourcq. With the building of the canals the prosperity of Paris became even more closely linked to waterborne traffic, which was handled at various quays and basins along the river and the canal system, while river ports have developed up and down stream from Paris to serve the industrial suburbs, e.g. at Ivry, St Ouen, St Denis, and Gennevilliers.*

Close on the canals followed the railways. On the north bank the gaps east and west of Montmartre served as convenient routes ending at the great termini of the Gares de PEst, du Nord, and St Lazare, placed near the outer boulevards. The area enclosed in 1841 made much land available for building, and around the canal basins and stations gathered warehouses and slaughterhouses, railway goods yards and repair shops, factories and gasworks, with tenements in the neighbouring quarters to house the workers. †

While Paris was thus expanding and its industries growing, wide changes were also being made to the plan of the city. These were initiated by Napoleon III, partly on aesthetic and partly on military grounds, and the work of reconstruction was entrusted to Baron Haussmann between 1854 and 1869. Narrow streets and congested areas gave place to wide boulevards and squares (Place de l'Etoile, Boulevard St Michel); parks and gardens were laid out (Bois de Boulogne); public buildings such as the Opera were erected; and the ring of outer boulevards was built on the line of the wall of the Farmers-General. This work was naturally costly, and Haussmann met with much opposition: it is to his persistence and the emperor's support that modern Paris owes its spaciousness and its vistas.

As a result of its industrial development, the population of Paris grew rapidly after 1861, increasing by 25 % in the next twenty years. From 1881 to 1901 the rate of increase declined to about 20%, and with the beginning of this century the period of rapid expansion was approaching its close. The population reached a maximum in 1921 with a figure of 2,906,000, but this represented an increase in the preceding twenty years of 7 % only. The war of 1914-18 no doubt had

* The waterways serving Paris are more fully dealt with in vol. iv, chapter vi, of this Handbook.

† The railways serving Paris are dealt with more fully in vol. iv, chapter iv, of this Handbook.

some influence on this slowing up of the city's growth, but decline had already set in before 1911. Since 1921, the population has fallen to 2,891,000 in 1931, and to 2,830,000 in 1936, a decline of roughly 2½%. To sum up: the net result of a century of growth, 1839-1939, can be seen by comparing Figs. 28 and 29.

Fig. 29. The built-up area in 1939

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 2 (Paris, 1934), and air photographs.

Water Supply

The growth of the city has been accompanied by improvements in the water supply. Until the nineteenth century, the domestic water of Paris was drawn mainly from wells or from the Seine. The latter was raised by pumps, the first of which, La Samaritaine, was set up at the Pont Neuf in the reign of Henry IV. Later in the seventeenth century other pumps were erected at Notre Dame and at Marly for the supply of Versailles. The public fountains were, however, supplied to some extent with water from other sources, e.g. the Belleville aqueduct, said to date from the fourteenth century, and the Arcueil aqueduct, restored by Marie de Medici. These supplies were

inadequate for the expanding city, and the first step taken to obtain water from a distance was the construction in 1822 of the Canal de l'Ourcq, which for some years served as an aqueduct as well as a navigable canal. About the same time, attempts were made to utilize artesian supplies at Grenelle and elsewhere, but owing to technical difficulties these wells were abandoned. It was not until the Second Empire that the problem was solved by the engineer Belgrand, who laid the foundations of the present system. The earlier superficial supplies, were now used for public and industrial purposes, while domestic water was obtained by tapping adequate and pure supplies at the sources of distant streams; this water was led through aqueducts or underground conduits to reservoirs on the suburban heights. The first to be completed, in 1865, was that from the sources of the Dhuis, a tributary of the Marne, which carries water 114 km. to a reservoir at Menilmontant. Later, water was similarly brought from the Vanne, an affluent of the Yonne, to Montsouris (173 km.), and from the Arvre, a tributary of the Eure, to St Cloud (120 km.). More recently, Supplies for the Montsouris reservoir have been obtained from the Loing and Lunain (73 km.), and the Vanne supplies have been augmented by the Voulzie aqueduct, completed in 1925.

The water from these sources amounts to about 450,000 cu.m. per day, which is still inadequate to meet the demand, especially in summer. Some 300,000 cu.m. have therefore to be pumped from the Seine and Marne, filtered and sterilized at Saint-Maur and Ivry, and either mixed with the other water or retained in separate reservoirs. In addition, very large quantities of river water, distributed through a separate system, are used by public authorities for street cleansing, etc., and by factories, and the maximum amount that can be removed from the rivers is being approached. There have been proposals therefore to seek further supplies from the water-bearing beds in the valley of the Loire, 200 km. south of Paris, which, it has been estimated, could yield 1 million cu.m. a day. It is probable, however, that the cost of the water thus obtained would be greater than that of water from the Seine after it has been filtered and pumped up to the reservoirs. Technical improvements have now made it possible to use artesian water in the outer districts: e.g. the artesian well sunk at Aulnay-sous-Bois in 1933 to a depth of 831 m. yields 5,000 cu.m. a day for the north-western districts.

INNER PARIS

Inner Paris: Population Changes since 1841

The slowing up of the rate of increase and eventual decline in the population of Paris was accompanied by a very rapid growth in the surrounding region, but before dealing with Greater Paris something

Fig. 30

Fig. 31

Fig. 30. The decline of population in the centre of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The decline in the central districts has been most marked in those which lie to the north of the river, particularly in the arrondissement of La Bourse and in the quartier of Les Halles.

Fig. 31. The growth of population in the outer districts of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The outer arrondissements of the city have increased considerably in population; more especially those which lie to the south. These areas have a number of light industries, and they also contain the homes of large numbers of the people who work in the heart of the city, many of whom have been displaced from the centre in recent decades. Outstanding among the districts of rapid increase are Clignancourt to the north, Buttes Chaumont and Menilmontant to the east, Vaugirard and Petit Montrouge to the south, and Auteuil and Passy to the south-west.

should be said of the distribution of population within the city limits. The city, that is, the area within the *enceinte* of 1841, plus the narrow military zone around it, the Bois de Boulogne, and the Bois de Vincennes, has an area of approximately 78 sq. km. In comparison with other great cities, this is relatively small, and the average density of population (37,000 per sq. km. in 1931) is consequently high. The administrative County of London, for example, has an area almost four times as great. Towards the end of the century, in 1896, the

corresponding figure was 32,000, so that the increase in density between 1896 and 1931 was 15 %. But this increase was not uniform over the whole city.

Two tendencies have been at work. With the continually increasing scale of operations, the heavier industries which had at first tended to concentrate in the northern quarters of the city began to move outwards into the open country, where ample and cheap sites, well placed for river and rail communications, were available. As a result, the Paris region became one of the most important in France for chemical, textile, and engineering works, and in 1931, 20% of French skilled workers were resident in the departments of Seine and Seine-et-Oise. Another tendency has been the so-called ⁱ flight from the centre'. The increasing demand for sites for administrative and commercial offices, banks, large stores, etc. in the centre has led to a rise in land values, and the consequent demolition of old residential property. Moreover, the improved facilities for travel to and from the suburbs have enabled city workers to live at a distance from their work. The insanitary condition of the former densely peopled quarters has also led the municipality to demolish properties and to move the inhabitants to new quarters on the edge of the city. The result of these developments has therefore been to reduce considerably the density of the resident population in the centre of the city, to increase that of the quarters on the periphery, and to bring into existence in the Greater Paris region large industrial and dormitory towns (Figs. 31-33).

Inner Paris: Distribution of Population

Comparing the distributions of 1896 and 1931, it is apparent that Paris can be regarded as composed approximately of three zones with individual characteristics, in which varying tendencies are visible.

The centre of the city, comprising the first seven arrondissements, covers the three historic components of *cite*, *ville*, and *universite*. The most densely populated of these arrondissements is the Temple, with over 50,000 inhabitants per sq. km., followed by L'Hotel de Ville and La Bourse, all on the north bank with 25,000-50,000 per sq. km. These constitute the financial and commercial district, with subsidiary activities such as newspaper production, and have all declined in resident population. This is particularly noticeable in La Bourse, where three of the quarters decreased by more than 35 % between 1896 and 1931. It is significant, as showing the piecemeal nature of this outward movement, that the fourth quarter remains one of the most densely

populated in the city, Bonne-Nouvelle with 101,500 per sq. km., and that the St Gervais quarter of the Hotel de Ville had in 1931 the exceptionally high density of 106,900 per sq. km. The fourth of these arrondissements on the north bank is the Louvre, with a lower density of 10,000-25,000 per sq. km. This includes the central markets (Les Halles), and also an area lying between the Champs-Elysees and L'Opera, which is the centre of 'haute couture', i.e. the production of 'Paris fashions'. The reason for this localization probably lies in the former focusing of court life around the Louvre and the Tuileries. The more popular 'grands magasins' lie between this point and the commercial area. Decline in population has also been very marked here, that of the quarter of the Halles having exceeded 50%. This area is also the home of highly skilled craftsmen, working on a small scale, e.g. costumiers, tailors, gold- and silversmiths, jewellers, and leather workers, who supply the demand for luxury articles.

The portion of the central area south of the river comprises the Pantheon, Luxembourg, and Palais Bourbon. The first two, corresponding to the University and 'quartier latin', had densities of 25,000-50,000 per sq. km.; the third, containing the homes of the aristocratic families of the Faubourg St Germain, of the diplomats in the shadow of the Quai d'Orsay, and of retired officials, is less heavily populated (10,000-25,000 per sq. km.).

The second zone, on the north bank, includes the arrondissements of L'Opera, L'Enclos-St Laurent, and Popincourt. This is the area of the Gares St Lazare, du Nord, and de l'Est, of the Canal St Martin, and consequently of commercial and manufacturing activity. Thus L'Opera and Popincourt were two of the three arrondissements which still retained in 1931 densities greater than 50,000 per sq. km. The quartier Rochechouart of L'Opera had the high density of 90,300 per sq. km., and was the sole area in this zone which increased during this period. The decline elsewhere was largely due to the spread of business houses and luxury shops in this direction from the centre: as a result, one district adjacent to La Bourse, the 'quartier de la Chaussee d'Antin', had decreased by more than 50%. The decline was less marked in Popincourt, which is largely a district of workers' tenements, with a large foreign element.

The third zone is that of the outer ring of arrondissements, mainly industrial and working-class areas, e.g. Batignolles, Montmartre, Chaumont, and Vaugirard, with a density in general between 25,000 and 50,000 per sq. km. This ring is broken at one point in the south-west by wealthier residential districts on the heights of Passy. Save

in a few minor districts, the population of this zone increased markedly since 1896. High increases of over 150% occurred in the manufacturing area of Vaugirard, and in Passy; several other quartiers increased by 65-120%. Though not the scene of heavy industries

Fig. 32. The density of population in the department of the Seine, 1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 20 (Paris, 1934).

In the city itself the greatest densities are found to the north of the Seine. In the remainder of the department the principal area of high density lies to the north-west on both sides of the Seine—at Neuilly, Clichy, Puteaux, Courbevoie and Colombes. This distribution largely reflects the distribution of industry in Greater Paris. B, Bois de Boulogne; V, Bois de Vincennes.

similar to those of Greater Paris, these exterior arrondissements have a variety of industries, such as the furniture factories of the Faubourg St Antoine (Batignolles), the boot factories of Belleville, and the light metal works of Charonne, apart from those more directly associated with the railways. These areas are also the homes of those displaced from the centre who work daily in the city and the west.

GREATER PARIS

Growth of Population

The boundaries which should be assigned to Greater Paris are not easy to determine precisely. During discussions in 1932 on future

Fig. 33. The growth of population in outer Paris, i.e. the department of the Seine outside the city limits, 1876-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 22 (Paris, 1934).

While the increase has been fairly general, it has been most marked to the north and north-east, and in some areas to the south. It will be noted that these areas lie mostly away from the city limits, for by 1876 the communes immediately adjoining Paris had already begun to experience a growth of population spreading outward from the city. These more remote communes, such as Gennevilliers and Colombes to the north-west, La Corneuve, Le Bourget, Drancy, Aubervilliers, Pantin, Bobigny and Villemomble to the north-east, and Gentilly, Villejuif and Sceaux to the south, had very small populations in 1876, and with the spread of industry in recent decades their growth has appeared all the more striking.

growth it was declared to consist of the department of the Seine, those communes of Seine-et-Oise and Seine-et-Marne within a radius of 35 km. of Paris, and a large proportion of L'Oise, forming an area

Fig. 34

of approximately 5,000 sq. km. with a population of 6,300,000. This deliberately included areas not then dominated by Paris: but whatever the exact boundaries, there is no doubt that the whole of the department of the Seine falls within Greater Paris, and recent censuses show how rapid has been the growth of its population. In 1881 the department, excluding Paris, had 530,000 inhabitants: this figure, by 1901, had nearly doubled (956,000), and trebled by 1921 (1,506,000); by 1936 it was 2,133,000, comparable with that of the city itself, with an average density of approximately 5,300 per sq. km. (Figs. 32, 33).

Development in these outer regions has spread along the lines of communications, absorbing long-established towns, and generally repeating the characteristics of the city's quarters thus extended—industrial areas on the lower, more accessible land, and residential suburbs on the higher. Four industrial areas are conspicuous : * (1) the north and north-eastern, comprising St Denis, St Ouen, Aubervilliers, and Pantin; (2) the west and north-western, spread along the winding valley of the lower Seine (Fig. 34); (3) the south-eastern, in the upper Seine valley as far as Choisy and extending west to the valley of the Bievre; and (4) the south and south-western, adjoining the city limits in the Gentilly, Vanves, and Arcueil areas, and extending westwards to Issy-les-Moulineaux.

North and North-eastern Industrial Suburbs. The first of these is of considerable importance. The basis of its development has been the St Denis canal, which, via the Canal de TOurcq, brings Pantin on the east within the area. The important industries of St Denis produce locomotives and wagons, engineering and electrical equipment, acids, fertilizers, soaps, etc., and along the Seine ships and barges are built. St Ouen to the south has a number of very diversified industries, generally of a lighter character—copper and aluminium

* For details of industry, see pp. 177-9.

Fig. 34. The industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The line of the 1841-5 fortifications is represented by the circular line of railway, except to the east where it is marked by a belt devoid of factories. Thus to the north, north-west and south-west most of the factories lie outside the city limits, while to the east and south they lie more within them. It is clear that the location of the larger factories is much more closely related to the river and to the railways than to the canals. The Port de Gennevilliers is a barge port of recent construction, in which the two existing docks will be followed by others, the whole system being designed to serve the growing industries of Colombes, Gennevilliers and Argenteuil.

goods, tinned foods, furniture and pianos, gloves from skins. The industries of Aubervilliers, La Courneuve, and Pantin are predominantly chemical, ranging from oil refining to perfumes and toilet articles, while the by-products of the Villette slaughterhouses are used for the manufacture of tallow, margarine and leather. In these districts the available labour has attracted many minor factories,

Fig. 35. The metal industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

These include mechanical and constructional engineering and a variety of metal manufactures. The majority of these factories lie to the east and south.

producing, for example, glass and pottery at St Denis, and sewing cotton and tobacco at Pantin. These five communes form a block of over 240,000 inhabitants, which increased between 1921 and 1936 by approximately 15%, despite a marked decline in the depression following 1931. This manufacturing area is spreading north-eastwards towards the rail and air centre of Le Bourget, competing for the available land with the builders of housing estates, who have been particularly active around Drancy (Figs. 28, 35).

West and North-western Industrial Suburbs. The second great industrial group is in the west and north-west, established along the valley of the Seine. Immediately west of Paris is the centre of the French motor and aircraft industries, with the Citroen works at Grenelle and the Renault at Boulogne-Billancourt (Plate II). Here

Fig. 36. The electrical, automobile and aircraft industries of Greater Paris, 1939. Based on (1) *Carte Industrielle de la Région Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The concentration of these industries to the north-west and south-west is clear. Figs. 35 and 36 are complementary, and show between them all the metal-using industries. Fig. 35 shows mainly old-established industries; Fig. 36 shows newer industries.

expansion has been rapid, the population of the latter commune having increased from 68,000 in 1921 to 97,000 in 1936. Farther downstream, on both sides of the valley, extends a string of industrial concentrations combining the engineering and manufacturing activities of their neighbours to the north and south: Suresnes, Puteaux (armaments), Courbevoie, Levallois-Perret (motors and aircraft), Clichy (gas works and oil refineries along the river), and Asnieres (chemicals

and foodstuffs). The population of this zone exceeds 380,000, having increased by approximately 20 % between 1921 and 1936. Expansion has progressed in the loop of the Seine towards Argenteuil, notably around Gennevilliers, where there is a large electric power station fed by water- and rail-borne coal. Interlaced with these and standing on the higher ground are residential suburbs, e.g. Neuilly, Nanterre and Colombes (Fig. 36).

South-eastern Industrial Suburbs. The industrial areas are repeated on a somewhat smaller scale in the south-east along the Seine valley through Ivry and Vitry, where there are large power stations and gasworks. Vitry, however, still continues to grow flowers for the city markets, whilst Choisy manufactures linoleum, paper and china. Here live a population of some 120,000.

South and South-western Industrial Suburbs. Another industrial belt extends to the west, skirting the city limits as far as the Seine; its features are the tanneries and laundries in the valley of the Bievre around Gentilly which perpetuate the early use made of its waters, and Issy-les-Moulineaux, with its power stations, munition and cement works, breweries, and tobacco factories. This sector has a population of over 200,000. From its western end a series of small towns continue southwards over the broken plateau, and house thousands who work daily in Paris; these towns, interspersed with market gardens, carry the boundaries of Greater Paris beyond Sceaux. The recent electrification of the railway line serving this area may be expected to stimulate the further development of dormitory estates.*

Eastern Residential Suburbs. In this circuit of Paris one sector has so far been omitted, the eastern, which has become the predominantly residential area of the outskirts, beyond the factories along the eastern border of the city. Extending over the gentle and formerly wooded hills north of the Marne as far as the boundary of the department are numerous residential towns such as Vincennes, Montreuil, and Fontenay-sous-Bois, with islands of orchards, vegetable and flower gardens, scarcely touched by industrial development. Nearly a quarter of a million people have their homes in this sector of Greater Paris. Similar expansion has taken place along the valley of the Marne, the tide of building progressing from one loop of the river to the next as far as Nogent. The peninsula between the Seine and the Marne is occupied by the working-class suburb around Alfortville comprising some 75,000 inhabitants. In the first great loop of the Marne is the garden city of St Maur (57,000); in the next Champigny (27,500),

* See vol. iv, chapter iv, of this Handbook.

and again in the next Nogent and Le Perreux (together 45,000), developments all consequent on the breaking up of large estates towards the end of the last century. Market gardening is still carried on to some extent, but except around Alfortville and Maisons-Alfort there has so far been little industrial development.

Regional Planning

This development of the Paris region has been haphazard and unco-ordinated. Factories and housing estates are intermingled: the new quarters of the expanding towns are often unprovided with adequate roads, drainage, or water supply: valuable agricultural land has been built over: and natural amenities have been destroyed. This has resulted from the lack of a central authority, the constituent communes being largely independent and without the means to develop in an orderly way. In 1932 a law prescribing a 'projet d'aménagement' for the whole region was promulgated. A general directing plan was drawn up and presented in 1934, with which the local schemes were to conform. It covered the lay-out of the main roads, open spaces, the use of the land and the regulation of buildings, public services, and the protection of sites. The scheme for communications provided for five radial motor roads in conjunction with an outer ring at a distance of some 20 km. from the centre.* For several reasons, among which the conflict of local interests is not the least important, progress with the scheme has been slow.

Attempts have also been made from time to time to check the continued concentration of industries, particularly aircraft works, in the Paris region, as this was considered to be strategically dangerous. In 1931 a fund was instituted to assist the removal, if required by the Air Ministry, of aircraft factories to a particular zone, and the scope of this measure was afterwards enlarged. Three years later the Departments of National Defence ruled that works thereafter established in the region should in general be excluded from their supply lists, and in 1938 official approval was required for the siting of new munition factories. It does not appear that this movement had made any considerable progress before the outbreak of war, one obstacle being the disinclination of the workers to migrate with the factories.

BIBLIOGRAPHICAL NOTE

(1) An account of the geographical factors important in the development of Paris will be found in the following articles and books:

(4) The series of maps produced by the *Societe de Documentation Industrielle* includes two very interesting maps of Paris and its satellite towns: *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); *Carte Industrielle de la Grande Banlieue (Seine-et-Oise, Seine-et-Marne)*, 1/320,000, with insets of Argenteuil, Montereau, Versailles, Corbeil, Persan-Beaumont, and Melun, 1/20,000 (Paris, 1927). See vol. 1, p. 249, of this Handbook. A detailed map showing the density of population in Paris and the Paris region in 1931 can be found in the *Atlas de France*, Plate 72 (Paris, n.d.).

Chapter III

AGRICULTURE

Introduction: Wheat: Other Cereals: Root Crops: Minor Crops: Wine and other Beverages: Market Gardening: Livestock: Working Population: Land Tenure: Legislation: Forests: The Vichy Regime: Bibliographical Note

INTRODUCTION

France is a country highly favoured by nature from the point of view of agricultural production. Of its working population, 35% are engaged in agriculture, and the urban areas are to a great extent fed by home-grown food. A map showing density of population exhibits a remarkable continuity in distribution; only in the highest parts of the Alps and the Cevennes and on the sandy forested stretches of the Landes are there any considerable empty areas. Cultivation penetrates far into the highlands of the Alps, the Vosges and the Jura, following the terraces of the river valleys; it covers the lower platforms of the Central Massif; it renders return, however meagre, even to the dense population of the poor acid soils of Armor in Brittany. If pastoral pursuits and forestry are included, there is hardly a corner of the country left unproductive.

Climate, soil and relief have greatly contributed to this high degree of land utilization, and to these factors must be added the late development of French industry. Both climatic and soil conditions present considerable variety. Exposure to Atlantic winds precludes the harsh winter conditions of more northerly and more continental areas, so that the sheltered bays of the Breton coasts are able to grow early vegetables for export. The extension southwards to Mediterranean shores and the protection afforded by the Cevennes and the Alps against northerly winds give to France a share in Mediterranean products, and have made possible the large-scale cultivation of *pruneurs*; yet, except in the Rhone delta and the eastern-facing valleys of the Pyrenees, the summer drought is not sufficiently prolonged to make cultivation entirely dependent upon irrigation. In the east of the country there is an approximation to continental conditions of agriculture, with the cultivation of maize, hops and tobacco in the lowlands. Finally, the ample development of mountain and plateau in the south and south-east with Atlantic-facing slopes is the basis for pastoral and forest industries.

A generalized view of the soils of France is difficult, partly because of the variety of soil types within a small area, partly because centuries of intensive cultivation, marked even by the transference of soil from one locality to another in barges, has made the present distribution in some areas almost artificial. Despite this, certain predominant soil groups are apparent. The most important contrast is between mountain and lowland soils. The former vary from the rich soils of the volcanic districts of the Central Massif through the moderately fertile calcareous soils of the Jura to complete poverty in parts of the Alps and Pyrenees. Acid soils, too inaccessible for economic liming, must be content to produce such 'poor man's crops' as rye and buckwheat. The lowland soils are equally variable—from the poor sands of the Landes and the sands underlain by clay of the Sologne to the rich alluvial deposits in the river valleys. The prevalence of limestone and chalk ensures large areas of warm, well-drained land; the distribution of *Union* on these high, limestone plains of northern France provides a fairly heavy, loamy soil, suitable for wheat, sugar beet and other root crops. Sunny, south-facing slopes on well-drained limy or gravelly soils produce vines as far north as the river Aisne (Fig. 46). Alluvial river terraces, especially when covered with loessic deposits, are intensively cultivated throughout the land. Ill-drained valley bottoms, moorland, coastal marshes and mountain shoulders or 'alps' provide meadow and permanent pasture.

Upon these diverse soils the intensive cultivation of the small farmer has in many places developed a specialized agriculture, but taking the country as a whole, the yield per hectare is a moderate one for western Europe. It is considerably lower than the yield in such countries of intensive peasant farming as Holland, Belgium and Denmark, and also appreciably lower than the yield in the United Kingdom and Germany, as shown in the following table:

	Yield (quintals per hectare) 1933-7 average			No. of livestock per 100 ha. of cultivated land, permanent meadow and pasture, 1937	
	Wheat	Barley	Oats	Cattle	Pigs
France	15'3	14'3	14'0	45	20
United Kingdom	22'8	20'6	20'4	48	36
Germany	22'2	20'9	19'9	71	83
Belgium	26'5	26'1	26'5	88	52
Holland	29'6	28'7	23'9	109	71
Denmark	31'3	28'4	25'9	93	111

From *Annuaire Statistique*, 1938 (Paris, 1939), which gives *Tableaux Retrospectifs* for a number of countries.

A comparison of the densities of "livestock likewise reflects the different agrarian economies of these countries. Figs. 37 and 38 show the percentages of arable land and grassland respectively in each department in 1938. The proportion of the total agricultural land devoted to each type of farming activity is shown in Fig. 39. The adjoining table summarizes the agricultural production of France.

Summary of Agricultural Statistics, 1938

	Hectares	Quintals (except where otherwise stated)
Cereals:		
Wheat	5,050,199	98,010,002
Oats	3,245,257	54,574,380
Barley	759,223	12,907,804
Buckwheat	261,366	2,422,894
Rye	631,096	8,111,314
Maize	340,290	5,786,067
Millet	9,212	88,266
Other products:		
Potatoes: New	113,235	9,266,727
Others	1,425,000	173,145,000
Sugar beet	319,000	79,800,000
Fodder beet	976,000	382,600,000
Flax	38,000	238,000
Tobacco	18,100	33,166,280 kg.
Hemp	3,802	41,873
Grapes	1,567,000	60,300,000 hl.
Hops	1,600	21,3'00
Cider	—	34,600,000 hl.
Market gardening	437,000	—
Olives	—	333,000
Livestock:	Numbers	
Cattle	15,622,000	
Sheep	9,872,000	
Pigs	7,126,000	
Horses	2,692,000	
Milk	133,241,000 hi.	

The source of this and of other tables in this chapter (except where otherwise stated) was *Statistique Agricole Annuelle* (Paris, latest edition refers to 1938).

WHEAT

In few parts of France are to be found the cool damp conditions that preclude the successful growing of wheat, as in western Britain, and as a result the area under wheat is half that under all cereals. The age-long localization of grain varieties enables most soils that are cultivated with intensive assiduity to be used.

The more important wheatlands (those with an average departmental production of over 2½ million quintals per annum) are situated in the departments to the north and east of Paris (Fig. 40). These areas

Plates 12, 13. Farms in the Bourbonnais

The Bourbonnais lies on the northern edge of the Central Massif between the rivers Cher and Allier. Plate 12 (above) shows the large establishment typical of a former social system; the fifteenth-century *Maison du Maître* lies adjacent to the dwellings of the *metayers* on the left. It is more common for the former to have a separate existence as a chateau. Plate 13 (below) is of a small farm more typical of modern French agriculture.

mainly comprise low limestone plateaux providing a well-drained subsoil covered with fertile surface loams. Wheat is also cultivated intensively on the alluvial terraces of the Seine and its tributaries (Plate 15). Districts with over 15.5 quintals per hectare stretch from the Seine valley to the Belgian frontier. Other areas of high yield are Languedoc, especially on the lava soils, the basins of the middle Rhone, the lower

Fig. 39. Utilization of agricultural land, 1938

Charente region in northern Aquitaine, and the upper valleys of the Mayenne and the Sarthe. Next come the coastal plains of western Brittany, Normandy, the Alsatian terrace lands, and the terraces of the lower valleys of the Alps and Pyrenees. The mountainous regions, together with the coastal regions of the Landes and the Mediterranean, are least important, although even there small areas of relatively level land are utilized (Plate 19).

The area under wheat decreased towards the end of last century as less favourable lands went out of cultivation. Between 1914 and 1918 the decline was rapid due to the ravaging of the north-east by war. Since 1919, the gradual recovery of these areas has been balanced by

Fig. 40. Production of wheat in quintals per 100 ha. of each department, 1938

a steady decline in the south and in other districts such as Normandy, where wheat occupied in 1933 only two-thirds as much land as in 1913. The latter decrease was due in part to the competition of dairy farming. As a result, the total area under wheat has remained relatively constant since 1923 but with a slight tendency towards decline. There has been some restriction in wheat growing as part of a general policy

of avoiding over-production. In 1933, producers were put on an area quota based upon an average of the three preceding years. The yield per hectare, although obviously masked by good or bad harvests, has

Fig. 41. Production of cereals, 1924-38

risen steadily, partly because less favourable lands have gone out of cultivation and partly because of an increased use of fertilizers (chiefly of superphosphates, potash, basic slag, etc.). Thus, although the area under wheat has declined by about 20 % since 1913, the increased yield has resulted in six harvests (those of 1925, 1929, 1932, 1933, 1934 and

Plate 15. Arable farming in Beauce

A photograph taken east of Chateaudun, showing the broad, flat, almost treeless expanse of intensively cultivated land.

Plate 16. Sheep-folding in Beauce

As in Britain, sheep folded on stubble or roots are an essential part of the arable farming economy of limestone regions such as this.

Plate 17. The Champagne Plain

View eastwards from Mt Aime, about 30 km. west of Chalons-sur-Marne. The level or gently undulating plain is between 100 and 150 m. above sea level. Hedgeless cultivated fields alternate with strips and rectangular blocks of planted pines.

Plate 18. Grain elevator near Castelnaudary (Aquitaine)

France is largely self-supporting in grain, and in consequence large quantities are stored at inland towns and not necessarily at the ports, as in Britain. The majority of elevators are owned by co-operative societies, in this case by the *Greniers reunis des agriculteurs Lauraguais*.

Maize yielded 5¾ million quintals in 1938, and it is important only in the south-west where conditions are moist, warm and virtually frost free. It is grown mainly as a fodder crop, and large supplementary quantities have to be imported. Small quantities are cultivated throughout eastern France—a reflexion of the increasing incidence of summer rainfall.

Millet. Only 88,000 quintals were produced in 1938, and of this Vaucluse, a department consisting largely of the Fore-Alpine limestone plateaux, grew almost one-half (41,000 quintals).

ROOT CROPS

Potatoes. Nearly 3 million hectares of ground are under roots and kindred crops, and almost half of that total (i.e. 44%) is occupied by potatoes. They are grown very widely for local consumption, and as the total crop exceeds the requirements for human consumption much of it is fed to pigs or used in the manufacture of alcohol and starch. Two districts specialize in the crop, namely, Brittany, which produces new potatoes, and the area around Strasbourg. Up to 1932, France exported a large amount of early potatoes, especially to Great Britain, but the extension of the Colorado beetle into Brittany has considerably reduced this trade.

Beet. Both fodder beet and sugar beet are grown to a considerable extent in France, roughly in the proportion of four to one respectively. Fodder beet is grown widely in the northern plains, chiefly for the fattening of stall-fed animals. Sugar beet is localized in the extreme north and around Paris (Fig. 43). The beet is grown on large farms in conjunction with wheat, both crops benefiting by the rotation.

Although many sugar refineries were destroyed during the war of 1914-18, the general rise in the standard of living since then has almost doubled the consumption per capita of sugar; the number of refineries is still below the 1914 total, but their output is much greater. The total number of refineries in France is 111, and of these seventy are situated in northern departments. The changes in this area are summarized below:

Refineries in Operation

	1912-13	1920-23	1928	1938
Nord	40	13	13	13
Pas de Calais	24	8	12	12
Somme	33	7	9	14
Oise	20	16	18	18
Aisne	51	11	13	13
Total for five northern departments	168	55	65	70

Fig. 44. Production of wine in hectolitres per 100 ha. of each department, 1938

At the same time as home production increased, sugar imports from the colonies increased almost fourfold compared with pre-1914 totals. As sugar stocks accumulated and the price of beet fell, an agreement was negotiated in 1931 between growers and refineries whereby the price of beet was fixed relatively to the price of sugar, and the refineries accepted voluntary quotas. At the same time the French colonies undertook to limit their shipments to 13 % of the home-produced total. Thus the industry achieved a certain equilibrium without state control, and the area under cultivation has fluctuated but little.

In addition to the utilization of the beet crop for sugar-refining, large quantities are sent to distilleries for the manufacture of alcohol.

MINOR CROPS (Fig. 45)

Flax is grown in the north-eastern departments in the Scarpe and Lys valleys, where a multitude of watercourses makes flax-retting easy. It does not, however, occupy more than 1½ % of the total arable land of the two most important producing departments of Seine-Inferieure and Nord. After a revival which reached a maximum in 1929 (79 % higher than in 1913), economic depression hit the industry, and in 1931 21,000 ha., almost two-thirds, went out of cultivation. The crop has been revived in recent years by a substantial state subsidy and has shown a striking increase since the lowest yield in 1932. In 1938, it was again above the 1913 total.

Tobacco is grown under state regulations and with a subsidy to a small but increasing extent in the south-west (Plate 20), in the two Rhine departments, and to a much less extent in the north-eastern departments and in those of Savoie, Isere and Drome. In Alsace it forms one of the two main crops of the reclaimed Rhine flood-plain—hops being the other.

Hemp is grown to a very small extent by state subsidy in the Loire valley, but in no department does it exceed more than 0.5 % of the arable land

WINE AND OTHER BEVERAGES

Production. France is the most important wine-producing country in the world, although Italy has a greater area under vineyards. But the French yield per hectare (401.) is almost twice that of Italy (22'11. per ha.), and in the production of fine wines France stands alone.

The vine, while not unduly exacting, as it is able to withstand periods of frost, requires a moderate rainfall in spring and early summer with strong continuous sunshine during the late summer and autumn. It grows very widely (Figs. 44, 46) on most types of soil, preferring well-drained stony or gravel soils. The effective northern limit of

Fig. 45. Production of flax, hemp and tobacco, 1924-38

the vine is shown on Fig. 46. The bleak uplands of the Central Massif are obviously not suitable, while the southern Landes and western Pyrenees are subject to warm moist air which encourages mildew. It is interesting to note that the marginal areas of the north, where exceptional and intensive care is necessary, produce some of the best vintages.

Plate 19. Grain harvest in upper Dauphine

Almost every patch of level land in the mountains, snow-covered in winter, is utilized in summer to produce crops of hay, grain or potatoes.

Plate 20. Tobacco cultivation near Beynac (Dordogne)

The rolling limestone country of eastern Aquitaine yields good soils on well-drained slopes. Most of the small farms have a field of tobacco (a carefully cultivated and remunerative crop) and a number of fruit trees.

Plate 21. A Champagne cave at Reims

Storage at even temperature in caves hollowed out of the chalk assists the maturing of the

Vine growing is mainly in the hands of small-scale cultivators, as a vineyard in full bearing fetches a high price per hectare. In 1924, 82 % of the 11 million growers who declared their output had holdings smaller than 2 ha. The remaining large holdings are found chiefly in the Garonne-Dordogne area, where famous Chateau vintages are

Fig. 46. Main wine-producing centres

Based on *Guide Michelin*, p. 28 (Clermont-Ferrand, 1939).

produced, a few in the Loire valley, and a very small number in the Champagne district. Many of the vintage wines such as those of Burgundy are grown by small cultivators and blended by large merchant firms.

Normally over half of the French output comes from the Midi. The grape grown is largely the *petits vins* cultivated on an extensive scale, and it provides the cheap *vin ordinaire* so widely consumed within

the country. The centres of the Midi wine industry are at Beziers, Nîmes, Perpignan and Montpellier (Plate 21).

The second great wine-producing area is in the south-west, and follows closely the valleys of the rivers Garonne, Dordogne and Charente, with Bordeaux as headquarters. About a quarter of the French total comes from here. Four distinct localities produce the high-grade vintage wines. The Medoc region yields fine clarets; south of Bordeaux is the Graves area; on the hills north of the Dordogne lies St Emilion; finally, the much smaller Sauternes district lies on both sides of the Ciron, a tributary of the Garonne. In south-western France are the brandy-distilling areas of Cognac, including the greater part of the departments of Charente and Charente-Inferieure, and the less important Armagnac district in the department of Gers, south of the Garonne.

Another group of wines are the Burgundies, which come from lower Burgundy (the Chablis district), the Maconnais and the Beaujolais; the most important area is the Cote d'Or, between Dijon and Chagny. Here the soil and climate are exceptionally favourable, and owing to scattered villages and the large number of small growers the wines differ widely. About one-twelfth of the French total is produced in this district (Plate 23).

The Champagne area lies in the department of Marne. The four main districts are (1) the slopes of the limestone hills known as the Montagne de Reims; (2) the Cote des Blancs south of the river; (3) the Marne valley itself; (4) and, finally, the lower slopes of the chalk escarpment in the extreme east of the department. The wine, which is essentially an artificial product blended from the output of all of these districts, is the result of careful culture, pressing, fermenting, maturing and blending. The production, however, is inconstant and constitutes a very small proportion of the French total, averaging only about a quarter of a million hectolitres (Plate 21), although in a 'good vintage' year the value is considerable.

Another important wine-producing district is in the Loire valley. The chief areas are in Anjou and Touraine, which yield such famous wines as Vouvray and Saumur; the coastal departments produce white wines such as Muscadet, and the rest of the valley produces large quantities of *vin ordinaire*. The production averages about 5 million hl., about one-twelfth of the French total.

Alsace-Lorraine is also a small producer of wine. The vines are grown on the lower slopes of the Vosges and in the eastern valleys, sheltered from winds and with sufficient sunshine (Plate 24). Much

of the wine is of ordinary quality, but such white wines as Muscatel, Riesling and Turckheim are exported.

Finally, in the Jura a number of notable wines, such as Ch&teau-Chalon and Arbois, together with much *vin ordinaire*, are produced.

Output. The area under vines grew steadily to a maximum of 2,447,000 ha. in 1874; the production of wine for market reached a total of 83.8 million hl. in the following year, a figure which has never again been reached (Fig. 47). Only about 3 % of this total was exported, but in value it was a much greater proportion of the whole. By 1879, production had sunk to 25.8 million hl.; this startling decline was due to the ravages of the *Phylloxera*, an insect native to the United States which had been introduced into Europe between 1858 and 1863 with American vine stocks. The insect multiplied at an enormous rate and attacked the roots of the highly susceptible European stocks, thus tapping the flow of sap and destroying the

Fig. 47. Production of wine and cider, 1830-1938

vine. Over a million hectares of vineyards were destroyed in France, and the financial loss is estimated to have been much greater than the indemnity paid to Germany after the Franco-Prussian War. The pest was overcome by (1) the large-scale introduction of a relatively immune American stock upon which the French vine was grafted, (2) the injection of carbon bisulphide into the ground, and (3) winter flooding where practicable. But the quality of subsequent vintages suffered, and in many localities vine growing was permanently abandoned. By 1911, an area of some 1½ million ha. was under the vine, producing about 45 million hl., and this area has remained relatively stable.

But although the *Phylloxera* was conquered, the wine industry never went back to its previous prosperity. During the years of low production, Spanish, Italian and North African wines made considerable headway. Algeria, being within the French customs territory, rapidly increased its output and sale in France. In addition, the cultivation of the vine in other parts of the world, notably in

South Africa, Australia and South America, caused further decline in French wine exports. South American wines hit especially the export of *vin ordinaire* from Bordeaux to the Latin republics.

The diversion of labour from agriculture during 1914-18 left* the vineyards open to disease, and in 1915 two-thirds of the crop was lost owing to mildew. Since that time the industry has recovered somewhat, but it has been hit by the heavy and increasing English excise duties, by Prohibition in the U.S. between 1920 and 1933, after that by the relatively small import quota allowed by the U.S., and by the general world economic crisis, wherein wine as a luxury product suffered severely.

As wine is the principal drink of the country, it is likely that the total amount produced is very many times that exported. But the home consumption has fallen greatly, owing to the general economic crisis, to unduly high prices, and to the greater adoption of other beverages such as beer and cider. Between 1931 and 1933, many of the great proprietors became bankrupt and their estates were broken up for sale. Since 1933, however, there has been some degree of recovery.

Beer and *cider* are the principal beverages in the areas where the vine cannot be successfully grown, although the first is increasing as a drink generally. *Beer* is produced chiefly in the north and east, *cider* in the north-west. Hops are grown in Alsace and Burgundy, but from the latter area they are sent to the breweries in the Nord and Rhine departments. Both the area under cultivation and the total yield fluctuate considerably. *Cider* is the normal beverage of Brittany and Normandy, and is produced in the apple-growing departments that border the English Channel. The chief feature about the yield is its variability (Fig. 47). Thus the yield in 1938 (34.6 million hi.) was more than twice that of 1937.

MARKET GARDENING

In many parts of France climate and soil, together with intensive skilled labour, have resulted in the localization of special crops. Adjacent markets in large towns have encouraged the large-scale production of 'perishable' commodities which command a good price. With the organized development of fast main-line trains with refrigerator cars (notably by the P.L.M.) and of motor transport, district surpluses have been sent farther afield. Thus Vaucluse and Var are able to send fresh produce to Paris, while a large amount of table fruit,

Plate 22. A vineyard near Narbonne (Aude)

Extensive vineyards in the Midi yield vast quantities of *petits vins*, grown and processed for the production of cheap *vin ordinaire*.

Plate 23. A Burgundy vineyard

The typical unit of production in the wine industry of Burgundy is the *dos*, of relative y small extent, from which the vintage derives its name—in this case Clos-Vougeot. Behind the chateau is the escarpment of the Cote d'Or.

Plate 24. Vineyards at Ribeauville (Alsace)
Alsatian vines are grown on the lower south-facing slopes of the Vosges.

cut flowers and other luxury produce from Provence appears in the London markets. As a result, in 1938, 143,042 people were engaged exclusively in the cultivation of fruit and 39,084 people in the cultivation of flowers. Of the total area devoted to horticulture in 1938 (that is, about 437,000 ha.) 304,000 ha. were cultivated for subsistence and the remainder for the production of cash crops for market—vegetables, fruit, flowers and shrubs (Plate 25).

Vegetables. In mild damp regions, such as the sheltered bays of Brittany and the Marais Poitevin, early products (*primeurs*), notably cauliflowers, new potatoes, onions and tomatoes, are cultivated for markets in Paris, England and the industrial north-east of France. The lower Rhone valley offers similar possibilities over a longer period of the year, and in Provence and Roussillon all types of early vegetables for salads are grown. In many districts, vineyards have been uprooted to make room for the more lucrative production of *primeurs*. Here irrigation, protection from the mistral by cypress and wattle fences, and smoke screens against frost are necessary (Plate 26). Around the large towns, market gardening and glass cultivation produce vegetables for the urban markets. In certain districts, notably round Bordeaux and Metz, peas, beans, asparagus, etc. are grown for canning and bottling.

Fruit. In a climate which has much sunshine fruit growing will clearly be important. The commercial production of fruit is carried on in many areas, and once again localized specialization is the case. Notable features are fruits for canning and crystallizing in Gascony, high-class dessert fruit of all kinds in the Rhone valley, cherries for bottling and sugaring in the upper Rhone area, black currants for making *cassis* round Dijon, almonds, figs and citrus fruits on the Mediterranean coast, walnuts in Isere, chestnuts on the Central Massif and the olive on the south-facing terraces of the Midi. The last is near the northern climatic limit and frosts may be destructive, but some oil is produced for margarine and soap as well as for export in a refined state. As in most Mediterranean lands, much olive oil is used locally for a wide variety of domestic purposes in place of animal fats.

Flowers are cultivated on the Cote d'Azur for making perfume and for the 'cut-flower' export trade; the centre is Grasse (Plate 27). Another example of large-scale specialization is the production of roses in Brie and Provins.

Silk. The cultivation of the mulberry may be linked with market gardening. It is cultivated on the lower slopes of the middle Rhone valley and of the Mediterranean coast, but the production of home raw

silk has decreased greatly. The cottage industry of silkworm rearing was halved between 1913 and 1936, largely due to competition by imported raw silk from Piedmont, Syria and the Far East. Production of silk is carried on in seventeen departments, the most important being Gard, Drome, Ardeche, Var and Lozere (see pp. 239-40).

LIVESTOCK

There are three types of natural pasture in France, namely, the upland type, the lowland *bocage* type, and the smaller areas of coastal saltmarsh.

The summer upland pasture is very varied. It includes the *alpages* or *alps* between the permanent snow-line and the tree-line (Plate 28). Animals are taken there from the valleys in early summer to graze until autumn. Other varieties of upland pasture include on the one hand the scanty herbage of the limestone Causses and the heath pastures of crystalline uplands, and on the other the better pasture of the well-watered lower plateaux such as Limousin, and of the rich volcanic soils of parts of the Central Massif.

The lowland *bocage* type is found where the rainfall is evenly distributed throughout the year and where conditions are mild, as for example in Normandy, Brittany and Vendue. The rank grass is suitable for cattle grazing. In general, too, hay meadows are conspicuous features in the broad clay vales that separate the higher limestone plains in northern France.

The third type is saltmarsh pasture found notably in the Crau and Camargue districts of the Rhone delta, and along the Vendee and Breton coasts.

The distribution of permanent pasture is shown on Fig. 38. The rearing of stock is, of course, not confined to these natural pastures, but is carried on in many places in conjunction with arable farming (Plate 16).

The number of cattle has risen slowly from 1875 to 1938, with but little break during 1914-18, and has stabilized at about 15 ½ millions. Sheep, however, decreased sharply during that period to just under 10 millions and are still significantly below 1913 figures; and pigs also declined, although they recovered their pre-1914 numbers in the next twenty years. The large war-time losses of horses had been almost made good by 1929.

Cattle are reared in most parts of France (Fig. 48), the least important area being along the Mediterranean coast, although even

Fig. 48. Distribution of cattle per 100 ha. of each department, 1938

Fig. 49. Distribution of sheep per 100 ha. of each department, 1938

there the Camargue is rather an exception. One important cattle area is the Armorican peninsula, despite the high proportion of ploughland and the low proportion of natural pasture. The Cotentin department of Manche has a greater density of cattle than any other in France; its cattle average 91 per sq. km. compared with the general French average of 29; the corresponding figures for milch cows are 51 and 17 respectively.

On the Central Massif, cattle are reared in the departments of Cantal and Haute-Loire, and in the more northerly departments of Allier and Saone-et-Loire (the natural pastures of Charolais (Plate 32)). An outstanding breed is the Salers. The animals are grazed in summer on the pasture of the volcanic soils of the plateau and are hay fed in the valleys in winter. Other important districts are in Picardy and Artois, in the Vosges, in Savoy, where the Tarentaise breed are kept, and in the Pyrenean foot-hills. Transhumance, that is the seasonal movement of animals to the high pastures in summer, is practised in nearly all upland areas.

Dairying is most important in Normandy, the Charente, Jura and Savoy. On the whole, production is backward and milk yield low, due to the multiplicity of breeds which hinder the organization of breeding societies, to the lack of a farming aristocracy interested in scientific breeding, to insufficient supplementary feeding of roots and oil-cake, to the prevalence of disease such as tuberculosis, to bad housing, and to lack of co-operation. Only in the Charente, and to a less extent in Normandy, Savoy and Jura, is there much co-operative organization. Although far below Danish or Dutch standards, Charente butter fetches the highest price on the Paris market.

Co-operation in the Charente

	No. of societies	No. of members	No. of cows	Milk handled, million litres	Butter produced, tons
1883	1	90	330	0'6	31
1908	112	67,026	165,021	246	11,636
1928	134	87,694	263,303	446	19,647
1938	134	77,820	271,539	447	19,775

From P. L. Yates, *Food Production in Western Europe*, p. 267 (London, 1940).

Other parts of France have a number of small-scale co-operative dairies but primitive independence is more usual. By far the greater **part of** butter and cheese is made on the farms or in the dairy chalets in the mountains. Such varieties as Gruyere in Savoy and Jura,

Plate 25. Market gardening at Chatillon (near Paris)

In the Paris suburbs, as around many great cities, vegetables are intensively cultivated.

Plate 26. Cultivation of *primeurs* at Chateau-Reynard (near Avignon)

Early vegetables are protected against the mistral by tall hedges of osiers.

Plate 27. Flower cultivation near Grasse (Alpes-Maritimes)

The south-facing slopes below the ramparts of the hill-top village of St Paul are divided by wattle fences into sheltered plots, where flowers and aromatic shrubs are grown for the perfume industry.

Fourme and Laguiole in the Central Massif, and Gerojne-Munster in Lorraine are almost entirely farm-made. In the north there is an increasing output of factory cheese, although much is still farm-produced by individuals; named varieties include Brie, Camembert, Pont l'Eveque, Livarot and Maroilles (Fig. 50). The increase in production which rapidly overtook consumption after 1918 inevitably

Fig. 50. Main cheese-producing districts

Based on the *Atlas de France*, Plate 40 (Paris, 1934),

led to a decrease in prices, accentuated very markedly by the rapid increase in imports. As a result, quota regulations were imposed to restrict imports of butter, cheese and margarine, and a subsidy in 1935 helped to finance the butter export trade. The milk industry is almost wholly unorganized owing to small-scale production, and only in Paris is there any large marketing organization.

Meat. The production of meat is secondary to milk but is not unimportant. The increase in numbers of animals in post-war years has

resulted in a supply sufficient to meet the home demand; some animals were even exported to Italy.

A large proportion of the meat is veal, which is very widely produced because many cows are calved for the sake of their milk; the calves are slaughtered young to save the cost of feeding. There is a certain amount of specialized bullock fattening, especially in the north, where store cattle brought from the Cotentin, the Charolais and Limousin are fattened indoors on sugar-beet pulp and oil-cake. The chief market for fat stock is at La Villette in Paris. Provincial slaughterhouses on a larger scale have been tried, but have failed owing to the small-scale production and the seasonal fattening system which results in long periods of inactivity. The rearing and training of bullocks for draught purposes (Plates 34, 35) and for the plough goes on in most places, but it is a special occupation in the farms of the Central Massif.

Sheep are reared mainly in the departments around and to the north of Paris, in the Central Massif where Aveyron and Lozere are the chief departments, in the Rhone delta and along the Pyrenean foot-hills (Fig. 49). They are also reared on the rougher pastures of the Cotentin, on the saltmarshes of the coast of Brittany and Normandy, and on the drained marshes of Deux-Sevres, Charente and Charente-Inferieure. In the Crau and Camargue districts of the Rhone delta extensive grazing is practised, and flocks are sent to the Alpine districts of Dauphine and Savoy, often by rail, for the summer months (Plate 30). In most of these districts sheep are kept both for wool and mutton. In the Causses, milk of sheep is used for cheese making, and there are over 500 concerns making the well-known Roquefort cheese (Plate 33).

The total number of sheep in France has declined drastically, and in 1938 there were only half as many as in 1900. Among causes to which this decline is attributable are the increase in wages and consequent difficulty of finding shepherds, the disappearance of biennial fallow in the southern part of the country, and low wool prices. As a result there is a large import of sheep, chiefly from Algeria, and of wool.

Pigs. Production is almost entirely unorganized and is devoted to supplying local markets. One or two areas, including Brittany, the Limousin district, Lorraine and Artois, have a certain degree of specialization for ham production, especially where they utilize skimmed milk and whey from the dairies. Apart from those, pigs are kept on a small scale as a secondary source of food almost everywhere but especially by poorer peasants. They are fattened for slaughter in

Fig. 51. Distribution of pigs per 100 ha. of each department, 1938

Fig. 52. Distribution of horses per 1000 ha. of each department, 1938

late autumn and constitute the winter meat supply. Although the quantity sold to the public has increased, over 40% is still consumed on farms. War-time slaughtering between 1914 and 1918 caused a rapid decrease, but since then numbers have increased steadily and the 1938 total slightly exceeded that of 1913 (Fig. 51).

Horses, etc. Despite the extensive development of mechanical traction and the virtual disappearance of horse-drawn vehicles in towns, the horse has held its own since 1918 after the heavy war-time losses. The total number in 1938 was 83·6% of that in 1913. The chief horse-rearing areas are in Brittany, where Finistère has more head (20) per square kilometre than any other department; then come Mayenne and the north-eastern departments (Fig. 52). The animals are bred largely for ploughing.

Mules and asses are used extensively as beasts of burden, there being 135,000 and 85,000 of them respectively in 1938. Mules are used in the south-east and south-west of the country; numbers of donkeys are to be found in Manche and Calvados in the north and in the northern part of the Central Massif, especially in Corrèze.

Other Livestock. Goats and *basse-cour* animals, that is poultry and rabbits, are kept largely as supplements by the small farmers, yet the total value is estimated to be about two-thirds that of the entire wheat crop. One or two goats are often kept to provide milk for those who cannot afford a cow, or maybe a few goats are pastured with the cattle. In some areas to the south of the Loire and in the Rhone valley the goats-milk is made into well-known local cheeses. A number of large farms near Paris produce eggs commercially, but the remainder of the home market is supplied by a very fluctuating yield from the general farms; only about 10% of the eggs that appear in the market are imported.

WORKING POPULATION

In 1931, nearly 7 million people were engaged in agriculture and allied pursuits (Fig. 53), representing approximately 35 % of the working population (Fig. 55); of these just over 3 million were male. The total represents a decrease of over 1·6 million on the 1911 figures, as shown by the following table:

Millions of workers engaged in agriculture

	Male	Female	Total	I
1896	5·7	2·8	8·5	
1911	5·3	3·2	8·5	
1931	3·1	3·8	6·9	

(Excluding Alsace and Lorraine)

From P. L. Yates, *Food Production in Western Europe*, p. 283 (London, 1940).

Fig. 53. Distribution of agricultural population per 100 ha. of each department, 1931

Fig. 54. Changes in rural population, 1881-1931, by departments

Statistics from which these figures and also Figs. 55, 56 were drawn were taken from vol. 1, part 3 of the *Recensement general*, 1931 (Paris, 1935).

The large decrease in male agricultural workers is striking; the less marked although considerable total decline is partially compensated by the persistent increase in female labour. This decline has not been uniform over the whole of France. Between 1881 and 1931 the numbers of rural dwellers actually increased in three departments (Fig. 54), but in no case by as much as 5 %. During the same period the most marked decrease was in the departments of Seine, Seine-et-Oise and Alpes-Maritimes where the agricultural population was halved, and in the departments of Rhone, Pas-de-Calais, Meurthe-et-Moselle and Belfort where the decrease was between 40 and 50%. In thirty-six departments the decrease was less than 10 %, notably in Brittany, the Loire valley and the Central Massif. The rural exodus is of long standing; it has been a feature of the mountainous parts since the middle of the last century, but it became more general after 1881. This was due to a variety of causes, including the abandonment to stock of poorer lands, the increase of machinery, the decay of rural industries, the drift to the more attractive work and wages-of the towns, and a birth-rate even lower in rural areas than the generally declining French rate, the result maybe of efforts to reduce the effects of divided inheritance. Yet agriculture is still by far the largest occupational group, and since 1930 the number thus engaged has started to rise again as a result of industrial unemployment. In 1931, 60% of all those employed in agriculture were their own masters either as owners, tenants or *metayers* (see p. 131), while the remaining 40% were labourers or employees in some capacity. Of the latter, 71 % were male and 29 % were female, either workers on the land or farm servants. In 1932, an inquiry into the question of agricultural wages yielded the following results:

Average daily earnings in francs

	1924	1928	1930	1932
All labourers	14-80	20'60	2250	2235
Male labourers		18'94	20'85	20'75
Wagoners		21'56	23'73	23'00
Female labourers		14'20	15'41	15'38
Female servants		13'58	14'74	14'72

The trend of these wages, namely, a steady rise to 1930, then a slight fall, has followed very exactly the trend of wages of other occupational groups. The above figures are averages for the whole country but differ widely in different districts. The proximity of large cities, industrial areas or coalfields necessarily forces agricultural

Over 39%	20 - 29%
34 - 39%	9 - 20 %
29 - 34%	Under 9%

Over 50% farmed by tenant.
Over 50% farmed by metayer.

Fig. 56. Systems of land tenure, 1932, by departments

wages up to meet the industrial competition for available labour. Thus around Paris the average wage per annum in 1937-38 was 14,050 fr., but in Ariège and Hautes-Alpes the figure was only about 4,000 fr. Average pre-1939 French agricultural wages (about 20s. to 25s. per week) compare favourably with Belgium (18s. to 22s.), but very unfavourably with Great Britain (33s. to 40s.).

Most people engaged in agriculture live permanently on the farms where they work, but there is some seasonal movement. This consists partly of a small shifting semi-urban, semi-rural population and partly of a seasonal influx of foreign labourers, but in no case is it great in amount, as the harvest on the characteristic small-holding merely involves the intensive and lengthy labour of all members of the family. The census of 1929 gave a total of over 800,000 men and women of French nationality employed temporarily in agriculture, that is, one-eighth of the total agrarian workers.

In 1929, there were a quarter of a million foreign agricultural workers in France, of whom half were permanently employed. Spaniards, Belgians and Italians from the adjoining countries formed the bulk of this labour, but Poles, chiefly because of their low standard of living and willingness to work for a very small wage, were also numerous. The Poles work mainly in the sugar-beet areas of the north-east, while the Spaniards and Italians are found along the Mediterranean littoral. Full details of the foreign elements in France are contained in Appendix I, pp. 375-92.

LAND TENURE

Farmland in France is cultivated by an owner-occupier, or by a tenant-farmer, or by a *metayer* or 'share-tenant' (Fig. 56). The proportions of these in 1929 were as follows:

	% of holdings	% of area
Owner-occupiers	75	60
Tenants	20	30
<i>Metayers</i>	5	10

From P. L. Yates, *Food Production in Western Europe*, p. 277 (London, 1940).

The owner-occupiers are in the great majority in the south and east, where many departments have 90% of their cultivable land farmed by the owners.

Less than one-third of the total agricultural area of France is cultivated by tenants, although in five departments of the Seine valley more than 70 % is cultivated in this way. In this area farmers and landlords

Plates 28, 29. The hay harvest

In mountain areas the hay crop is a vital part of the farming economy. Plate 28 (above) shows the method of stacking in the Alpine district, where high winds and heavy rain are frequent; Plate 29 shows a mountain farm in the High Vosges of Alsace.

Plate 30. Mountain pasture in Haute-Savoie

Plate 31. Cattle grazing in Brittany

These two plates show the contrast between scanty mountain pastures, where sheep roam over wide areas, and rich cultivated *pratnes artifielles*, where restricted grazing by tethered **cattle is part** of a mainly arable farming economy.

co-operate to maintain the farms in the best possible condition. In other parts of France, such as the Sologne, farming is spoilt by sport, and the farmers, who are entitled by law to receive compensation for damage, often live on the compensation.

Metayage, or share-tenancy, is a system whereby the landlord provides the farm, implements and livestock and in return takes half the produce as rent. The landlord may be a landed proprietor, an absentee capitalist, or sometimes a small farmer who has invested in a second holding. There has been a considerable decline in the system in the last hundred years, and only in the departments of Landes and Allier is over half the agricultural area cultivated on this system. Its disadvantages are obvious, for it encourages wasteful cultivation; the tenant is tempted to put in as little and to take out as much as he can; insecurity never makes for good farming. A hard-working single man can earn more as a hired labourer and therefore save enough to buy his own holding in due course. The *metayer* is usually a man who has no capital but can utilize the labour of a large family.

France is a country of smallholders; in 1931, 85.1% of the total number of holdings were less than 10 ha. in area. On the other hand, the remaining 14.9% of the holdings occupy nearly three-quarters of the total area of France (excluding forests).

Size of holding (in hectares)	Number of holdings	% of total	Area of group (hectares)	% of area of France (less forests)
0-1	2,235,405	39.2	1,327,300	2.6
1-10	2,617,558	45.9	11,244,700	22.8
10-50	764,461	13.5		
50-100	52,048	0.9	36,806,800	74.6
Over 100	33,280	0.5		
Total	5,702,752	100	49,378,800	100

The larger holdings are almost entirely in the north-east (Fig. 57) and are devoted to growing sugar beet. Around Soissons, for example, the farms are from 300 to 400 ha. The number of large holdings has decreased during the last 40 years. Some of them were broken up in 1918 in default of heirs, or because of shortage of labour or lack of capital. Holdings of under 2.5 ha. are mainly in the vine areas. The most typical is that of 10-25 ha. with a mixture of horticulture, agriculture and livestock, and this type occupies nearly half the total cultivated area. The smaller grower is favoured by the Wheat Growers'

tax which was imposed in 1938 and which is on a sliding scale, rising sharply with an increase in the area of the holding.

The problem of the prevention of the continual splitting up of the holdings due to the laws of inheritance has given rise to many difficulties. While the principle of the equal division of property among the children had been practised in some districts before 1789,

Fig. 57. Average size of holdings in hectares, 1930, by departments

Napoleon's Civil Code enforced this. Although some children might be bought out, subdivision inevitably increased. In the department of Meuse, for example, one farm of some 30 ha. was divided into about 2,000 'parcels', with each peasant owning twenty or thirty scattered about the whole holding. There have been various attempts, none of them very successful, to meet this problem (pp. 133-4).

LEGISLATION

France is divided for the purposes of agricultural administration into eight regional offices responsible to the Minister of Agriculture. A regional office in turn has the general supervision of the departmental offices within its area. A departmental office is directed by five representatives of the agricultural interests of the department and is managed by trained agriculturalists.

General Policy. The state's agricultural policy has consisted of a spasmodic series of relatively unrelated schemes. Direct subsidies have furthered large schemes such as rural electrification, water supply, road and rail improvements, and the use of fertilizers. There has been a gradual improvement in agricultural inspection, in the registration and compilation of production returns, and in the establishment of agricultural schools, research stations and breeding establishments.

Finance. Almost one-half of the agricultural population are borrowers who obtain credits from the National Mortgage Bank (*credit fonder*) or from the numerous agricultural credit banks, through which direct state loans are made. Other sources are the solicitors and merchants connected with agriculture, and the Joint Stock Banks, together with private organizations such as Peasants' Unions, the Durand Banks and the co-operative banks of Alsace and Lorraine.

Labour. Some effort has been made to improve the lot of the rural worker. Between July 1929 and November 1932 a series of regulations dealing with the accommodation of labourers were passed, and in March 1932 the extension of compulsory family allowances to include agricultural workers was effected. In December 1932, the law enforcing the submission of disputes between employer and employee to a conciliation board (*consdl des prud'hommes*) was applied to agriculture. It had already been operating for industrial disputes. To strengthen the employer's position, a law was passed in February 1932 whereby a former employer might secure damages from the new employer in the event of a labourer breaking a contract to change his job. This helped to check the evil of enticement.

The Size of Holdings. Efforts have also been made to meet the problems of division of property by inheritance. In 1908, a law was enacted which allowed a holding not exceeding the equivalent of £320 to be registered as inalienable. But this figure was much too low and subdivision had already gone too far when it was reached. Regrouping with all its saving of time and efficiency could only really be accomplished by energetic individuals through sale, marriage or

exchange. Clearly, a single person could spoil any scheme by withholding his consent. A state-sponsored regrouping scheme in 1919 helped but little, as a majority vote of a commune was still necessary before the state could take the necessary steps. When a commune agreed to a regrouping scheme, the government paid 80 % of the cost of regrouping as a direct subsidy. As a result, about 600,000 ha., chiefly in the north-east, were regrouped between 1919 and 1929. In 1935, a further act was passed to simplify the procedure for regrouping, but as the initiative is still largely left to the peasants little has been done.

Protection. The state has also pursued a strong policy of protection and encouragement of home agriculture by imposing tariffs and import quotas on a wide variety of agricultural produce, including specified items from particular countries. The problems of over-production at home have been partially tackled by restrictive area quotas and by marketing regulations. The measures adopted towards the two most important commodities, wheat and wine, illustrate the nature of the difficulties and the efforts to overcome them.

In the case of wheat, the outstanding problems in recent years have been those of over-production and of marketing. During 1931 and 1932, imports were still much above average (Fig. 42) in spite of the tariff, while subsequently there were good crops in the years 1932, 1933 and 1938. Efforts were made to limit surpluses by putting growers on an area quota; a 'Wheat Commission' was instituted to dispose of surplus supplies and a minimum selling price was fixed, although in practice it could not be enforced. In 1935, the establishment of new flour mills was forbidden. In 1936, a 'Wheat Office' with local branches was set up to deal with problems of over-production and marketing. Growers were compelled to state the area they had sown and the quantity of wheat harvested; apart from their own consumption, they had to sell to the local co-operative society (Plate 18) or to a licensed dealer. In 1938, the harvest was good and a surplus was the result. To deal with this a tax on producers was imposed.

The great over-production of wine, the obstacles to its export and increasing imports have led to several legislative attempts to meet the situation. In July 1931, it was enacted that no individual or undertaking in France or Algeria owning 10 ha. or harvesting 500 hi. should plant any more vines for 10 years, and fines were imposed on excessively high amounts. The first of these measures was abrogated in the same year as its imposition, but it was re-enacted in July 1933, when for a period of 5 years no increase of vineyard area was to be

Plate 32. Grazing on the Charolais plateau

Rich pastures on Jurassic limestones are utilized to fatten the famous white Charolais beef cattle.

Plate 33. A cheese cave at Roquefort (Aveyron)

Cheeses, made from sheep's milk, are matured in caves hollowed out of the limestone cliff, on the slopes of which the town of Roquefort is situated.

Plates 34, 35. Ox transport in southern France

Oxen are used extensively as draught animals in many parts of France, notably in Aquitaine. Plate 34 (above) is a scene in St Jean-de-Luz. Plate 35 (below) shows the collection of seaweed on the coast at Hendaye; it is spread on the nearby fields as a fertilizer.

allowed. In July 1932, a system of 'blocage' was put into operation whereby the government was empowered in the event of over-production to fix the amount of wine to be put on the market. In that month no grower harvesting 500 hi. could sell a quantity of wine exceeding two-thirds of his total harvest. Each producer of wine had to register and obtain permits for the sale of produce, while the local Marketing Committee had to release the output as the market could absorb it and thus maintain a minimum price. The whole system hits the larger producers who have to release part of their crop to distilleries at low prices, while the small producers are able to sell at much better prices in the open market. In 1934, cultivators were paid the equivalent of up to £40 per acre for the destruction of their vineyards, but they were not to replant or to grow certain other specified crops, notably tobacco, flax and sugar beet.

Owing to the fact that the majority of growers have holdings less than 1 ha. and are therefore largely untouched by legislation, the schemes to restrict vineyards are ineffective; there was more land under vines in 1938 than at any time since 1913.

French growers have long agitated for a restrictive quota on imported Algerian wine, as the lower costs of production and the large export from the non-wine-drinking Mohammedan population, together with freedom from foreign import duties, affects adversely the home industry. But up to 1936 no legislation had been effected.

FORESTS

Of the total surface area of France about 10½ million ha., that is 19·4%, are forested (Figs. 58, 59). Similar figures for Great Britain are 1¼ million ha. and 5·4% respectively. The woodland is scattered over the whole country, with concentrations partly in certain parts less suitable for cultivation, notably on the bleak exposed uplands and on coarse sandy soils, and partly in preserved state-owned areas. Sixteen departments in 1938 had over 30% of their total area under wood (Fig. 58). In some districts, however, chiefly in the north-west and north-east, forests which once existed on well-drained lowlands have been removed by centuries of intensive cultivation, and woodland now exists only as coppice.

Of the French total of 10½ million ha., 14·4% is state forest, comprising chiefly the afforested areas, and are well maintained by the department of *Eaux et Forêts*, which administers them under a code of forest law.

Another 20-9 % belonging to communes and public bodies are also administered by the same department, while the remainder (647%) is in the hands of private individuals. The proportions of coppice, deciduous and coniferous woods may be seen from the following table:

Forests of France, 1929. Thousands of hectares

Coppice	Deciduous	Coniferous	Total	Recently planted	Total
6,480	1,122	2,777	3,899	292	10,671

Fig. 58. Percentage of area covered with woodland in each department, 1938

The forests may be divided into three main groups, namely, the Mediterranean type in the south-east, the cooler temperate forest of the Atlantic seaboard and hinterland, and the upland forests. Although there is a considerable diversity, areas of certain dominant species may be broadly distinguished.

The major areas of natural woodland will first be considered, then the regions where extensive afforestation has taken place.

*Natural Woodland**(1) The Mediterranean Forests*

These may be divided into two groups, those in Provence and in Languedoc. In the former area, the Aleppo and maritime pines are indigenous, and occur in uniform stands. There are also many exotics and tropical plants in the parks and gardens of the Riviera coast. In

Fig. 59. Distribution of woodland, 1932

Based on the *Atlas de France*, Plate 38 (Paris, 1935).

Languedoc both coniferous and deciduous trees are represented; they include various species of pine, several varieties of evergreen oak and edible chestnut. Other deciduous trees scattered more generally are the lute-tree, some varieties of ash, poplars along the banks of the Rhone, planes, Montpellier maples and alders.

These southern woodlands have been extensively ravaged in this area by cultivation, by past exploitation for shipbuilding, by over-

grazing and by several disastrous fires. In many places a secondary growth has established itself—*garrigue* on limestone and *tnaquis* on siliceous soils. The words themselves are sometimes used to denote the type of country as well as the type of vegetation. *Garrigue* is found mainly to the west of the Rhone in Gard and Herault, on limestone plateaux averaging 150-300 m. but reaching 800 m. in places; they are also found behind Toulon. In *garrigue* the dominant plant is the stunted kerm oak, which grows in thickets, but many other plants thrive—grass, thyme, and more often shrubs like lavender, juniper and cistus (rock-rose). Areas of rock and stony soils bear the arbutus (strawberry tree), laurel and mastic trees, and the asphodel. The majority of these plants are remarkable for their strong scent. Thus *garrigue* country has a rich variety of plants, and belies a first impression of desolation and poverty. All *garrigue* plants possess drought-resisting features such as thorny structures, or leathery, shiny or curled leaves, or long ropts. The drought which limits the growth and type of vegetation results from several factors: a thin soil covering, the permeability of limestone rock, the rapid run-off of rainfall, and the high temperatures and excessive evaporation which prevail during summer when rainfall is lowest.

The *tnaquis* is less varied than the *garrigue*. The country east of the Rhone has more frequent silicious rocks (sands and marls), and here the maritime pine is dominant. These pine forests permit the development of a very dense shrub vegetation of cistus, arbutus and broom. Growing in a less permeable soil, the plants have not such pronounced drought-resisting features as *garrigue* vegetation. The dry nature of the vegetation as a whole and the resin secreted by the pines make the *maquis* particularly liable to the danger of fire.

These two vegetation groups have a complicated history. In Languedoc the *garrigue* is the work of man; the original natural vegetation included many woods of ilex or holm oak, protecting the thin soil which nourished them. Destruction of these valuable trees permitted soil erosion, and on the resulting stony uplands they were followed by thickets of stunted kerm oak. In places where many successive fires have occurred the *garrigue* is replaced by grass steppe, and with overgrazing even this fails to replace itself, and gives way to the final triumph of the asphodel. If, on the contrary, the grass cover is not grazed by animals, it is invaded by thickets of kerm oak, which eventually allow the return of the ilex oak, first in copses, then in forests (though a forest is rarely given time to recover in this way).

The kerm oak was formerly more widespread, and in the eighteenth

century many oaks still survived in the inland parts of the Maures. The progressive removal of these more valuable trees allowed the pine, a latecomer, to take root. The oak has been able to colonize successfully only the limestone country which is unsuited to pines. In the Maures and Esterel massifs, east of the Rhone, abandoned agricultural clearings are invaded first by kerm oaks, but these are in turn stifled by the pines coming back to reconstitute the maquis. Once the maritime pine has secured a foothold it rarely retreats; in spite of fire it replaces itself without human intervention, and the dense closed vegetation of the maquis which follows is able to stifle any oak seeking to re-establish itself in its former territory.

(2) *Temperate Forests*

The undulating plains and hills of the Atlantic seaboard and its hinterland are covered with deciduous trees except where coniferous afforestation has taken place. These temperate forests cover three-quarters of the total area of France and may be conveniently divided into two regional groups, namely:

(a) *Aquitaine and the south-western plain.*

(b) *The north Atlantic coast, the Paris Basin and north-eastern France.*

(a) *Aquitaine and the south-western Plain.* This area is climatically a transition zone between the maritime temperate and Mediterranean regimes, and as a result the vegetation exhibits transitional characteristics. Several species of the southern deciduous trees are found, including the cork oak on the siliceous soils south of the Garonne, the Montpellier maple as far north as Poitiers and Niort, the ilex oak and the pubescent oak in the south, and the pedunculate oak in the lower valleys. Elms and beech occur notably in the forests of Chize and Aulnaye. Conifers, apart from the great afforested Landes (see pp. 141-2), are represented by scattered patches of pines on the hills.

The natural forests on the whole are not extensive, as much of the region is under vineyards, market gardening or permanent grazing.

(b) *The North Atlantic Coast, etc.* The dominant species of this extensive zone are the pedunculate and English oaks, although most of the temperate deciduous trees are represented. Beech trees are common everywhere except in the Loire valley. The fine old domanial forests are largely made up of the two oaks. The mild winters allow the persistence to an unusually northerly latitude of some of the southern evergreen trees. Many conifers have been naturalized, especially on sandy areas such as the Sologne (see p. 142), but

only in rarer places on the uplands, notably in Alsace, are they indigenous.

Some of the largest individual forests other than the afforested areas occur in this region. They include the Forests of Orleans (34,344 ha.) and Fontainebleau (16,855 ha.).

(3) *Upland Forests*

The forests covering the bleaker upland areas are predominantly coniferous, although numerous deciduous trees, mostly beech and ash, occur on the lower slopes. Three main altitudinal zones may be distinguished which vary in height with the latitude of the upland. They comprise a lower zone of firs, pines and beech, a middle zone of larch and Arolla pine, and an upper zone where occur alpine meadows, bushes and isolated dwarf trees. As a rule, however, the tree-line is clear-cut and distinct.

In the Central Massif the main forests, occur between 600 and 800 m. and the upper tree-line is at about 1,200 m. The summits of the uplands range from 1,400 to 1,886 m. and are covered with alpine pasture. Besides a variety of pines, the beech dominates in the Morvan and Montagne Noire, and the sweet chestnut flourishes on the crystalline rocks.

In the Vosges and Jura the tree-line is at 1,200-1,300 m.; beyond this are summit moorlands and pastures devoid of trees. The forests of conifers are extensive on the plateaux from about 700-800 m., while deciduous trees, including maple, plane, mountain ash, mountain elm and beech, are scattered on the lower slopes (Plate 36).

In the Alpine regions the upward tree limit varies considerably according to aspect and district, from about 1,800 to 2,400 m. In the damper northern section the chief tree is *Picea excelsa*, while species of fir cover the valley sides and the lower pre-Alp summits. Below 1,000 m. occurs a mixed coniferous and deciduous woodland, including maple, elm, ash and birch. In the southern section the larch is much more abundant, but the fir and beech are less frequent because of the diminished moisture. The larch, Arolla pine and evergreen alder are often found near the upper limit of tree growth. The woods are less extensive than in the northern section.

The higher forests of the Pyrenees are similar to those of the Alps, the lower ones similar to those of Provence. The tree-line varies between 2,000 and 2,400 m. The cork oak forms extensive evergreen woods on the lowest slopes; higher up, where there is more rain, are dense thickets of kerm oak; chestnuts and beech grow up to 500 m.

with here and there ash and elm; varieties of fir and pine occur up to the tree limit.

Afforestation Policy

The extensive planting of trees as part of a definite state policy has been carried out in many parts of France in both upland and lowland areas. This afforestation has aimed at reducing the country's extensive imports of soft woods and pulp, at making good the forest areas ravaged in the last war, at fixing the sand dunes of the Landes and at combating rain wash and torrent erosion. Conifers are used almost exclusively for artificial plantation as they will grow in almost any physical environment, will reach maturity relatively quickly and will yield a variety of products. The upland areas so planted are chiefly in the Alps and the Central Massif, while outstanding lowland plantations are in the Landes, the Sologne and the *Champagne pouilleuse*.

In the *Alps* afforestation began in 1860 as a defence against soil erosion. By 1929, the state had purchased 189,768 ha. of land and had planted 110,000 ha. of these. A further 89,660 ha. are on schedule to be purchased as future state forests. An additional 32,000 ha. have been planted by individual owners with state help. In the Alps few extensive single state forests have been planted, as no arrondissement or commune is unwooded and afforestation usually takes the form of connecting scattered natural forest.

In the *Central Massif* the most notable work has been done in Aigoual south of the Cevennes, where between 1856 and 1931 the state acquired and planted 13,766 ha. Five-sixths are conifers, but beech, chestnut, ash and some varieties of oak have also been planted. The state delivered 65 million young trees between 1863 and 1933 from the nurseries in the Rhone valley to various communes in the Massif. In the Puy-de-D6me 22,000 ha. were planted between 1843 and 1934. On the Montagne Noire and the plateau of Millevaches (Limousin) future afforestation schemes aim at planting some 90,000 ha. of the total uncultivated area of 110,000 ha.

The *Landes*, which consist of sand dunes, marsh and gravel soils, were very scantily wooded from ancient times. At the end of the eighteenth century there were only a few scattered maritime pines and some dwarf oaks. The physical nature of the terrain made cultivation impossible. In 1783, a few experiments were made with little success, but in 1857 drainage by canals was begun in some places. In 1862, the department of *Eaux et For its* was given charge of the area to combat the invasion of the dunes. A dune wall 8-15 m. high

was built along the coast, about 150 m. behind the highest tide-mark. The hinterland was planted chiefly with maritime pine, and smaller plants were used to fix the terrain. This woodland now covers 956,000 ha. and is by far the largest and most continuous forested area in France (Fig. 59). Owing to a high resin content, the trees are not suitable for pulping; this resin is collected and forms a valuable product (Plate 37). The thinnings are used as pit-props; larger trees when injected with copper sulphate make durable sleepers; mature trees are utilized as constructional timber of all kinds. The necessary drainage has transformed the unhealthy malarious moorland and fen. Population is of course still small, as forestry maintenance does not require many employees, although there are open areas where maize is grown and dairy cattle reared.

The *Sologne* is covered with coarse sand which often lies on clay, and marsh with shallow sheets of water is common. An ancient forest of deciduous woods covered half of it in past years, but by 1800 it had been reduced to one-tenth of its former size. By 1830, however, the forest as a result of planting covered 120,000 ha., of which 72,000 ha. were coniferous. In the winter of 1879 and 1880, a disastrous frost killed most of the maritime pines, so when reafforestation began again other varieties of pine were first used and then Douglas fir. By 1914, the *Sologne* had 170,000 ha. of timber, but nearly half was felled during and immediately after the war of 1914-18. Although afforestation began again, in 1930 the total of 159,000 ha. was still substantially below the pre-war level; another 90,000 ha. are scheduled for planting.

The *Champagne pouilleuse* is over 700,000 ha. in extent; it is little cultivated as the soil is thin and chalky, and the land is utilized almost solely for grazing. Much work has been done by private initiative and many thousands of hectares have been planted with pine, birch, willow and alder, and with oak on the better soils. By 1914, 100,000 ha. had been planted, but these suffered badly owing to excessive felling during the war of 1914-18. Planting now has almost made good the losses.

The *Verdun district* in Lorraine was also terribly devastated during 1914-18. Even the rock was sometimes bared by explosives, and 14,000 ha. of forest were destroyed. By 1938, 12,400 ha. had been reafforested.

THE VICHY REGIME

The harvest of 1938 was good, and large surpluses of wheat and other cereals were stored for possible national emergencies (see p. no). In 1939, the areas under crops showed a small decrease, due largely to the disruption of economic life by the mobilization of September-October 1938. When final mobilization began in August 1939, the harvest was in progress. Although delayed considerably by the immense drain of man-power from the land, it was completed by older men and youths, by women, and in some areas by troops released for the purpose. The season was reasonably good; the areas of crops were usually well below the record high yield of 1938, but in general up to the average. The following table gives the areas and yields of the commodities for which figures are available; the 1938 figures are appended for comparison:

	938		1939	
	Area 1,000 ha.	Yield 1,000 quintals	Area 1,000 ha.	Yield 1,000 quintals
Wheat	5,050	98,010	4,727	78,000
Barley	759	12,907	799	9,980
Rye	631	8,111	648	8,060
Oats	3,245	54,574	3,242	43,540
Maize	340	5,786	329	5,230
Potatoes	1,425	173,145	1,382	150,000
Sugar beet	319	79,800	333	85,000

From official sources.

The armistice of June 1940, with its division into occupied and unoccupied territories, upset the internal agricultural equilibrium of the country. The north, where most of the wheatlands are situated, had to bear the burden of the German army of occupation; the hilly south could not feed itself in normal times. Only in Alsace-Lorraine, which was *de facto* incorporated into the Reich, and in the north-eastern plains did the Germans make any substantial effort to assist agricultural recovery. The agricultural situation was made worse by the large number of men held as prisoners of war, by the slaughtering of livestock for the army of occupation, by the shortage of fertilizers and vine sprays, and by problems of transport and distribution. The bad harvest of 1940, together with the increasingly close blockade, produced a considerable shortage of food during the winter of 1940-1; rationing of bread, sugar, butter, meat, wine, cheese, fats, potatoes, macaroni, rice and pulses was imposed. In spite of efforts by the Vichy government, the food situation continued to be critical,

and the winter of 1941-2 was a hard one for both unoccupied as well as occupied France.

The problem of food supply was naturally much more acute in the towns than in the country, and various schemes attempted to equalize distribution. Farmers were urged to co-operate with the government; quotas were levied, and bonuses paid for prompt supplies; rigorous measures were taken against the 'Black Market'. Illegal trading in foodstuffs became a vital social question in France; it was stated in December 1941 that supplies coming on to the 'Black Market' were as great as or greater than those reaching the legal markets. Large-scale hoarding by peasants was severely punished but with little effect. Malnutrition, especially among children, was very prevalent in the towns; the death-rate rose, and infantile mortality during the first half of 1941 trebled. Trouble culminated in the food riots of January 1942; they occurred chiefly in the southern departments of Hérault and Gard, where even the small rations could not be obtained. Supplementary rations were issued here and elsewhere.

The situation was helped slightly by shiploads of powdered milk, wheat and other supplies from America during 1941, which were allowed through the blockade by Britain on condition that the American Red Cross and American Friends' Service Committee guaranteed that the supplies should not fall into German hands.

The Harvests of 1940-1

Wheat (see pp. 106-10). Over two-thirds of French wheat is produced in the occupied zone. It was estimated that only about 3 million ha. were sown in the autumn of 1939 for the 1940 harvest—over 1½ million ha. less than in the previous year. Destruction of crops by the military operations in the summer of 1940 was not as great as might have been expected, owing to the mobility of the warfare and to the rapid decision. But even so, some wheat was damaged by fighting, and the flight of so many peasant families caused destruction by neglect. Much of what remained was harvested with the help of the German army. To the south, in the unoccupied zone, the harvest was the worst for many years. The total French crop of 1940 was about 42,500,000 quintals—as against the normal 75 million quintals. As a result, in October 1940 strict bread rationing was imposed in both the occupied and unoccupied zones.

In the autumn of 1940 some 4,100,000 ha. were sown, a 30 % increase on the previous year. During the early summer of 1941 small amounts of wheat went from occupied to unoccupied France,

but these were far below what was needed (the deficiency was estimated at 7-8 million quintals in the unoccupied zone), and at the end of May unoccupied France faced extreme hunger. The bread ration was decreased and adulterants were introduced into the flour. The Germans, however, released 2 million quintals out of supplies requisitioned for the army, and this enabled 3 million quintals to be sent by a barter agreement from occupied to unoccupied France; 700,000 quintals were imported from North America, and 145,000 quintals came from America. At the end of June 1941, the bread ration was restored to a normal level (275 grm. or less than 10 oz. per day). The 1941 crop was estimated to be about 65 million quintals, which was more than in 1939 but still well below average.

Other cereals (see pp. 110-13). Nearly all the *oats* are grown in northern France. The harvest of 1940 was poor and totalled only 30 million quintals, or about three-quarters of the 1939 yield. In 1941, the yield improved to about 35 million quintals. The amount used as fodder was drastically reduced, and Germany requisitioned large quantities. The poorer cereals, *millet* and *rye*, which are mainly grown in unoccupied France on the Central Massif, were a little below normal in both years, but they feed only a small proportion of the population. The Germans claimed an increase in the acreage of rye in the occupied zone. Most of the maize comes from unoccupied France. Some 3,400,000 quintals were harvested in 1940, that is, just over half of the previous year's total. No figures are available for the production of *barley*, but here again the Germans claim an increase in 1941 in the occupied zone; this cereal follows the trend of the wheat yield quite closely, so that the 1940 crop may be estimated at 4-5 million quintals, with about half a million more in 1941.

Potatoes (see p. III). The potato crop of 1940 amounted to about 90 million quintals, and in 1941 to about 120 million quintals; both compare unfavourably with the average pre-war yield of about 160 million quintals. In many parts of France potatoes form a staple part of the diet, and a shortage has serious consequences. In September 1941, the government tried to supplement the insufficient rations of bread and meat by as large a ration of potatoes as possible. Compulsory purchase quotas from producers were introduced, and fanners who refused to sell their quota to the government became liable to three years imprisonment. A bonus of 5 fr. per quintal was paid, and urgent appeals for co-operation were made so that requisitions would not be necessary. The Germans distributed small quanti-

ties of potatoes in 1941, ostensibly from their own but more probably from French stocks.

Sugar beet (see pp. 111-13). Almost all the land under sugar beet and all the refineries are in occupied France; the crop suffered considerable damage during the war and there has been a great shortage of sugar, with resultant stringent rationing. In 1940, only 114,000 ha. were harvested from a planted total of 271,000 ha., and the total produced was estimated at 46 million quintals; this figure compared very unfavourably with the 1938 total of nearly 80 million quintals. There was some improvement in 1941, and the output was estimated to be nearly 70 million quintals. The sugar ration in unoccupied France remained at 500 grm. (about 17 oz.) monthly, but that figure was still much below the peace-time consumption.

Wine (see pp. 113-18). The total yield of wine was about 85 million hl. in 1939; in 1940 and 1941, it was estimated to be about 60 and 45 million hl. respectively, which compared unfavourably with the normal average of 70 million hl. Most of the French fine wines, with the exception of those produced in the Burgundy district, come from occupied France. Most French *vin ordinaire* comes from the unoccupied zone, and this output has not been appreciably reduced. It was estimated that 10 million hl., or about one-sixth of the total peace-time output, were requisitioned during 1940 for the German army of occupation. The grapes of the famous vintage areas were grown and processed more casually to produce cheap wines for general consumption.

The industry suffered greatly in 1940 owing to the shortage of skilled labour, and the grape harvest was rarely completed. In 1941, disease was widespread due to the lack of copper sulphate for spraying; in Burgundy, for example, the grapes were almost completely ruined by mildew. On the other hand, vine growing in Alsace has benefited; the area of vineyards in 1940 was 16,000 ha., nearly 1,000 ha. more than in 1939. This development of Alsatian agriculture has been part of German policy. The 30,000 families engaged in viticulture have gained by the elimination of cheaper French wines, which had steadily reduced the Alsatian vine area in pre-war years.

In September 1940, the Vichy government introduced new regulations for vine growers. Every vineyard of more than 5 ha., or producing more than 500 hl., was obliged to grow crops other than vines on one-tenth of its land. Growers producing more than 200 hl. were to keep 20 % of their grape 'must' for turning into sugar, and those producing more than 50 hl. of pure alcohol had to keep the

grape pips for the production of vegetable oil. There was much trouble during 1941 over the distribution of wine, resulting in a clash between the interests of the growers and the government's wine policy. Wine growers asked for higher prices, for more government assistance, and for less requisitioning. General suspicion attributed the shortage of supplies to the sale of requisitioned wine by Germany through neutral firms in Switzerland and Portugal to America. The official explanation was that production for 1940-1 had been abnormally low while consumption had increased, and little had come from Algeria owing to transport difficulties. Severe rationing was introduced at the end of 1941; normal consumers were allowed 1 l. a week and heavy workers 5 l.

Other crops (see pp. 118-20). Efforts were made to increase the cultivation of vegetables generally—of haricots, of soya beans and of other oleaginous plants, of flax, of hemp and of green feeding stuffs. The chief disabilities were shortage of labour, of seed, of fertilizers, and of tools. The only conspicuous increase has been in the case of flax; the area of this crop was 65 % greater in 1941 than in 1938. Otherwise only in Alsace-Lorraine, where the Germans have supplied these wants, was produce up to pre-war standard. The development of agriculture in Alsace-Lorraine was dominated by Germany's needs; the area under tobacco, for example, was maintained by the German tobacco firms which purchased and prepared the entire crop. The winter cultivation of oil seeds (including rape), which had been negligible before the German regime, was increased to 1,900 ha. in 1941 and to 3,500 ha. in 1942. On the other hand, hop cultivation was reduced by 1,000 ha. to avoid competition in the German market.

Livestock (see pp. 120-6)

The majority of *cattle* in 1938 were in the north (see pp. 120-4 and Fig. 48), but large numbers were slaughtered to supply the army of occupation, which drew a large part of its meat from France. Shortage of imported feeding stuffs also caused extensive slaughtering. Unoccupied France in 1938 had only about a quarter of the total French cattle, chiefly dairy herds in the Central Massif, Alps and Jura. It was estimated that even if the total number of milch cows had not declined, the milk output would have been reduced by 15-20 % because of the shortage of oil cake and of other feeding stuffs. Thus there was a great shortage of milk, cheese and butter. In September 1940, cattle were redistributed to compensate areas where herds had been destroyed owing to the war. The German authorities tried to

replace the Lorraine livestock which had been destroyed during hostilities by importing animals from Germany, Holland and Denmark, and in December 1940, 11,000 head of cattle bought from Switzerland and Austria arrived in Strasbourg. Efforts were made in unoccupied France to grow lucerne and roots for fodder. Nevertheless, the total number of cattle in both zones decreased by 25 % between September 1940 and April 1941; in August 1941, it was stated that the herds consisted mainly of young animals which would not be suitable for slaughtering for a long time. By the summer of 1942, the herds of cattle had increased in number compared with April 1942, but the major difficulty continued to be shortage of feeding stuffs.

It was estimated that there was a deficit of only 130,000 *horses* (out of a total of 2½ million) after the armistice, but the German army requisitioned large numbers, and petrol shortage increased the need for horse transport. This deficit was reduced slightly during the winter of 1940-1 by transfers from the army and by imports from Algeria. There is little information about any other livestock, except that in July 1941 the numbers of *pigs* and *sheep* arriving at the Paris market of La Villette were respectively one-quarter and one-half of the total in the same month in 1938. This is probably indicative of peasant hoarding, although the number of pigs in 1941 was some 33-40 % below the pre-war level, due to slaughtering for immediate needs, while sheep were about 15 % below.

The government in September 1941 tried to improve the meat situation by organizing fodder supplies. A plan was drawn up specifying the amounts of barley and oats which each department had to deliver to the departmental agricultural committees for distribution among communes according to the needs of each region. Bonuses were given for quick delivery, and farmers who undertook to carry out government contracts for stock breeding received extra rations of fodder. Nevertheless, the meat ration for January 1942 was cut from 250 grm. (about 8½ oz.) weekly to 180 grm. (about 6oz.) in the towns, and to 125 grm. (about 4oz.) in the country; the extra meat ration for heavy workers remained the same. The cheese ration remained at 50 grm. (under 2 oz.) per week, and all fats remained at 450 grm. (under 1 lb.) per month.

Forests (see pp. 135-42)

After the armistice, the department of *Eaux et Forêts* had to face a large increase in timber consumption. This was due to an almost

complete cessation of timber imports, and to the necessity of using wood in large quantities to be made into charcoal for producer-gas engines, to manufacture cellulose needed by the greatly increased artificial textile industry, to manufacture wooden shoes because of the leather shortage, and as domestic fuel, as well as for all its normal uses of carpentering and furniture making. It was estimated that the amount of wood used directly or indirectly as fuel increased from 14'8 million cu. m. in 1939 to 30 million in 1941, and that the monthly production of charcoal increased from 15,000 tons before the war to 52,000 tons by the end of 1941.

Soon after the armistice, government forestry camps were established to fell timber on a large scale, and a law of August 1940 obliged all forest owners to increase by 50 % the number of trees they normally felled. During 1941 enormous areas of forested land were cleared. But it was increasingly apparent that this was leading to critical deforestation with its resultant evils of floods, soil erosion and avalanches, as well as to grave shortage in the future. Accordingly a law was passed in January 1942 to deal with reafforestation. It provided that from 250,000 to 300,000 ha. should be planted with trees during the next decade, particularly in the Landes, the Montagne Noire and the Millevaches plateau of the Central Massif. Certain districts would be delineated for compulsory planting, and the land-owners would be given the choice either of doing the work themselves with the aid of state subsidies, or of allowing the department of *Eaux et Forêts* to do it.

Labour and Land

An acute shortage of agricultural labour was experienced after the outbreak of war, because the agricultural population was mobilized far more drastically than the industrial. After the armistice the shortage was still worse, as of 1,800,000 prisoners taken by the Germans 1,200,000 were agricultural workers, and few of these have been released.

German Measures. German plans for French agriculture paid less attention to the needs of the French than to the need of a comprehensive plan to increase production through a more intensive exploitation of French resources. France had to supply a large part of European foodstuffs—chiefly fruit, vegetables, wine, wheat, oleaginous plants, flax and hemp. The Germans released prisoners in the occupied zone, and soldiers from the German army were used as farm labourers. The abandoned farms of north-east France were ordered to be

cultivated, and detailed instructions as to which crops were to be grown were issued. German overseers were appointed to farm large tracts of abandoned land, using large-scale mechanization. The Germans also ordered much land in the Maginot area, deliberately left derelict for many years, to be cultivated; it is estimated that about 50,000 out of 150,000 ha. were put under cultivation. Many of the people of Lorraine were assigned to abandoned or uncultivated land with a view to permanent settlement as part of the German effort to develop Alsace-Lorraine. Other measures included credit and loan facilities to assist the financial burdens of reconstruction, and agrarian taxes were lightened pending full recovery. In return for this assistance, the Alsatian farmers were required to produce crops in accordance with German plans.

Vichy Policy. French agricultural policy was dominated by two main objects: first, to supply the country with food and to keep down food prices; and second, to assist the farmers in every way possible and thereby strengthen the economic structure of the country. These policies have been carried out in both zones as far as possible, but to a much less extent in the occupied area. The Vichy government instituted a series of measures to meet the situation in the territory under its control, but most of these, however, have not been implemented.

Attempts were made to stimulate a 'back to the land' movement. All agriculturalists and rural artisans were as far as possible demobilized first. Agricultural Associations assisted in the repatriation of people to their lands, and in September 1940 2 milliard francs were advanced by the Treasury through local branches of the *Credit Agricole* to assist farmers in repairing war damage. Each commune was required to complete within two months an inventory of land left uncultivated for more than two years. The prefect of each department was then authorized to grant such land for a period of nine years to any person of French nationality who could offer adequate guarantees. Preference was to be given to relatives of men killed in the war. No rent was to be paid for the first three years, and after that it was to be only one-half that of similar farms in the same district. Farmers were encouraged to take school leavers, especially those from urban areas, as apprentices; there were 6,000 of these in 1941. The state promised to pay the farmer a subsidy of 900 fr. towards their training. Compulsory land service was instituted for young people between 17 and 21 as a temporary measure. In July 1941, a law was passed requiring the compulsory attendance of all

boys and girls not receiving other education at special agricultural courses. The state also assumed powers to requisition men, preferably urban unemployed with agricultural experience, and to draft them on to the land.

A large government works programme for agriculture was set forth in October 1940. It included schemes of electrification, water supply, drainage and land reclamation, and the building of co-operative factories and dairies. Schemes for land reclamation included the development of the Sologne district, and the reclamation of the Crau district in the Rhone delta by the *Compagnie Nationale du Rhone*, to which subsidies have been paid by the state.

Several measures concerned with the organization of the workers have been effected. In December 1940, an agricultural corporation was outlined, providing for the organization of all farmers and agricultural labourers into local unions within each region (see vol. II, pp. 265-71). These regional organizations were to be coordinated by a national committee. Specialized organizations, insurance and credit societies, and co-operatives, were all to be included within the framework of the agricultural corporation. During the winter of 1941-2 a committee of the *Conseil National* was engaged in drawing up the charter of the Peasant Corporation. The importance of the family holding and the development of modern methods through agricultural unions and co-operatives was emphasized. Official policy aimed at reducing the number of farm labourers by giving them holdings. Subsidies were granted towards the improvement of rural housing.

The Vichy government also made some effort to tackle the problem of divided inheritances (see pp. 132-4), and of the reorganization and regrouping of agricultural holdings. It was clearly impossible to carry out a policy of land resettlement in districts where each farm consisted of many scattered strips. In April 1941, a law was passed whereby the prefect could initiate schemes in any department without the previous necessity of obtaining the consent of a village majority. In each commune strips of land were to be grouped into more compact holdings by a committee appointed by the prefect. No strip after regrouping was to be more than 3 km. away from the farmstead. State help was given to provide new buildings for family holdings. In July 1941, the inheritance code was modified to allow small farms to remain undivided at the request of one of the co-heirs.

As a result of all these efforts, it was stated in May 1941 that nine-tenths of the land abandoned in 1940 had been brought back to

cultivation, and that since July 1940 the state had advanced 200 million francs directly to farmers and a further 200 million francs to Agricultural Credit Societies for reclaiming waste land.

BIBLIOGRAPHICAL NOTE

(1) Statistics, used both in the text and in the compilation of the maps, are given in two French official publications—the extremely detailed *Statistique Agricole Annuelle* (Paris) and the more summary *Annuaire Statistique* (Paris). Statistics relating to the agricultural population are given in detail for 1931 in vol. 1, part 3, of the French census, *Résultats statistiques du recensement général de la population en 1931* (Paris), and in a more summary form for 1936 in vol. 1, part 1, the only section so far published.

(2) General descriptive surveys of French agriculture are given in P. L. Yates, *Food Production in Western Europe* (London, 1940), part iv; in H. Ormsby, *France, A regional and economic geography* (London, 1931); in the *Report on France, Department of Overseas Trade* (H.M.S.O., London, 1934); and in L. Michael, *Agricultural Survey of France* (U.S. Department of Agriculture Bulletin, No. 37, Washington, 1938).

(3) Useful accounts of special regions or of aspects of agriculture are numerous; they include French government pamphlets, notably the *Monographies Agricoles* published by the French *Ministre de l'Agriculture*, the publications of the *Conseil National Economique*, and regional monographs by French writers.

Chapter IV

FISHERIES

Introduction: The Eastern English Channel: Normandy and North Brittany: South Brittany: The Bay of Biscay (south of the Loire): The Mediterranean Coast: Organization and Research: Bibliographical Note

INTRODUCTION

In view of the extensive coastline of France, it is not surprising that the French fishing industry employed in 1937 nearly 70,000 registered boat fishermen (*en bateau*), and about 50,000 part-time shore fishermen. Another 9,000 people were also employed in the preservation of fish and in associated activities; two-thirds of these were women.* Although the fishermen were distributed widely round the coasts, the table on p. 155 shows that the majority lived on the Atlantic coast south of Brest, and that three ports, namely, Concarneau, Lorient and Boulogne, had together nearly one-quarter of the fishermen of France.

The total catch, other than shell-fish, in 1937 was 352,000 metric tons, which compares unfavourably with that of other European countries, as the following table shows:

	1,000 metric tons		1,000 metric tons
Great Britain	1,108	Holland	263
Norway	1,012	Denmark	88
Germany	671	Finland	22
Iceland	322		

Two-thirds of the total French catch by weight is made up of five species offish—cod, herring, sardine, mackerel and tunny; yet 'other products', including finer varieties and shell-fish, form half to three-quarters of the total value, as the following table shows:

	Million francs	
	Total value of all fish	Value of ' other products'
1932	958	663
1933	927	597
1934	893	544
1935	761	516
1936	892	720
1937	1,142	674

* These figures refer to mainland France. Corresponding figures for Corsica and North Africa are included separately in the table on p. 155. It is not possible, however, to isolate the figures of Corsica and North Africa in the tables of total values and weights of individual fish on p. 156.

The proportion of the value of 'other products' was lower in 1937 than for many years, because of the unusually heavy catches of cod, herring and sardines (Fig. 60). This total of 1,142 million francs (to which Corsica and North Africa contributed 88 million francs) was just under one-third the value yielded by the coal mines of France, but it was only one-fiftieth the value of French agricultural produce. The corresponding British fishery figures for 1936 were approximately one-tenth for coal mines and one-twelfth for agriculture.

Fig. 60. Annual French catch of cod, herring, sardine, mackerel and tunny, 1920-37

From *Annuaire Statistique*, 1938 (Paris, 1939).

'Wet fish', as distinct from 'shell-fish', fall into two main classes—pelagic and demersal. The former live in surface waters or at no great depth, and occur in large shoals in the relatively shallow seas on the continental shelf. The more important of these in the French fisheries are the herring, sardine, mackerel and tunny, and the quantities

3,884	1,150	4,770	866	3,121	23,952	81,262
1,040	380	550	253	413	809	7,197

The source of this and of other tables in this chapter was *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

caught vary tremendously from year to year (Fig. 60). In 1937, the amounts of each were as follows

	Weight metric tons	Value million francs
Herring	64,682	88
Sardine	38,310	125
Mackerel	21,299	62
Tunny	10,658	54
Anchovy	7,547	10
Sprat	2,742	3

Demersal fish live normally at the bottom of the sea; this category includes both flat fish, such as plaice and sole, and free-swimming varieties, notably cod and whiting. Cod is the most important, both by weight and value, but a great variety of other demersal fish is caught. In 1937, the following quantities were landed:

	Weight metric tons	Value million francs
Cod (excluding oil)	65,512	154
Whiting	26,843	71
Skate and ray	14,068	37
Plaice	7,935	29
Sole	1,577	28
Congers	2,846	11
Turbot	1,203	11
Mullet and bass	1,139	11
Eels	1,025	4
Brill	417	4

In addition to these two main categories, the French official returns also include a total of 65,144 metric tons (valued at 200 million francs) of 'other fish', that is, of unclassified *poisson frais*, which are sold unsorted in bulk. Shell-fish, which are hardly comparable by weight, were valued in 1937 at 147 million francs; lobsters comprised 38 million francs, oysters 26 million francs, and shrimps 18 million francs. They formed one-tenth of the total value of French fisheries; the corresponding figure for Britain is only one-thirtieth. To these figures must be added large but unspecified amounts of fish which do not appear in official returns. In the first place, these take account only of fish sold in market, and the amounts consumed by the fishing population itself must be considerable. In the second place, inland and fresh-water fisheries (rivers, lakes and artificial pools) provide an important source of food in country districts.

During the last forty years the French fishing industry has experienced, but to a much less extent, the same centralization and industrialization, which has concentrated the British fishing industry at six main ports. Half the total French catch is landed at four

ports—Boulogne, Lorient, Dieppe and La Rochelle (Fig. 61). The first of these is pre-eminent; over a quarter of French fish are landed there, but even so it handles less than one-third of the annual total of Hull. If the value of fish is considered instead of its weight, Boulogne is still outstanding but less strikingly so, as it is responsible for about one-sixth of the total value.

Fig. 61. Weights of fish landed per annum at French ports, 1937

Based on the *Atlas de France*, Plate 53 (Paris, 1936), with statistics brought up to date from *Statistique Annuelle des Pêches Maritimes*, 1937 (Paris, 1938).

In 1937, there were more than 23,000 fishing craft registered along the French coast, including about 1,500 in Corsica and North Africa. Of this total, only 401 were steam-driven, 11,373 were mechanically driven by Diesel or by auxiliary motors, and 9,711 were sailing boats. The first category, however, amounted to over 92,000 metric tons, or more than one-third of the total fishing tonnage. It is significant

to compare (p. 155) the number of vessels and their total tonnage at Boulogne, Lorient and Fecamp, where most of the large steam trawlers have their base, with ports like S&te, Les Sables d'Olonne or Arcachon. Sete, for example, has more than three times as many craft as Boulogne, but the tonnage of the latter is ten times as great.

The French fishing centres may be conveniently grouped in five areas, as follows:

- (1) The Eastern English Channel.
- (2) Normandy and North Brittany.
- (3) South Brittany.
- (4) The Bay of Biscay (south of the Loire).
- (5) The Mediterranean Sea.

In each stretch of coast the fisheries will first be described, then the important fishing ports.

THE EASTERN ENGLISH CHANNEL

This area is characterized more than any other part of the French coast by the centralization and commercialization of the fishing industry. There are few little villages, such as are typical of Brittany, whose populations earn their livelihood by small-scale and often part-time fishing. Instead, there is a small number of fishing ports able to provide accommodation and fuel facilities for the large mechanized vessels. More than one-third of the total French catch is landed at these ports.

Herring. The entire French catch of herrings, about one-tenth of the European total, is landed along this coast. Herring fishing starts in May in waters to the east of the Shetlands; it has migrated to the seas off Flamborough Head by October, and reaches the Straits of Dover and the Channel in November. Formerly, the typical vessel was the *dundee*, a strongly built sailing boat of from 10 to 60 metric tons, but there is an increasing number of steam or Diesel drifters. These drifters are some 40 m. long, are of about 300 metric tons, and carry a crew of from six to eight. The herring are caught at night by series of drift nets (*raies*), each 50-60 m. long, which form an extended wall of netting kept vertical in the water by buoys and weights, and fastened by a series of ropes to a headline which is attached to the drifting ship. A large amount of herring is caught by trawling in the day time, that is, by dragging along the sea bottom a bag-shaped net kept open by a beam or by wooden trawl boards (*chalut a panneaux*). This takes place off the Shetlands

Plate 39. *Terreneuvers* at St Malo

St Malo is the home base for the *terreneuvers*, which fish for cod off the Grand Banks of Newfoundland. The vessels in the Bassin Duguay-Trouin are decorated with bunting for a religious ceremony before they leave in March for St Pierre and Miquelon.

Plate 40. Fish preserving at Concarneau

Large numbers of women are employed on a part-time basis in the numerous sardine and tunny preserving factories of the town.

Plate 41. The sardine fleet at Douarnenez

This view shows part of the large flotilla of *bateaux sardiniers* in the Grand Port. The fine meshed nets with their cork floats are hung from the masts to dry.

Plate 42. Tunny boats at Concarneau

The usual tunny boat is a strongly built *dundee* of some 40-60 tons; a notable feature is the *tangon* or rod, fastened to the base of the mast, to which the lines and hooks are attached.

from December to May, off Aberdeen from May to October, and in the seas off the north of Ireland and in St George's Channel from July to September (Fig. 62). It is a harmful (although lucrative) practice, as it spoils the grounds for other varieties of fish.

Mackerel. Many of the herring drifters are used at appropriate times of year for the mackerel fishing. The mackerel are caught in March off the south coast of Ireland, and the season ends in June off the Scillies. Thus the drifters are laid up only from January to March, and sailors sign under a single contract for about nine months.

Cod. Fecamp and Boulogne are the two chief centres for the cod fisheries or *grande peche*. These lie in distant waters off Iceland, Greenland and Newfoundland, and more recently in the Barents Sea. The amount of cod produced in 1937 was as follows:

Ground	Fish metric tons	Oil hectolitres
Iceland and north European waters	11,678	1,742
Greenland	15,280	5,390
Newfoundland	38,554	9,017

French fisheries in Icelandic waters were once very extensive, and vessels sailed not only from Gravelines but from Paimpol and St Malo on the Breton coast. In 1900, over 250 sailing boats, including both *dundees* and *goellettes* (a type of schooner), fished these waters, but in 1932 there were only twenty-one, including nine from Gravelines. These vessels left France about the middle of February, and reached Iceland in about 10 days. The *dundees* fished the east coast of Iceland from March to August, moving gradually north, while the schooners similarly worked northward round the west coast. The decline in the French Icelandic fisheries coincided with the disappearance of these sailing vessels, which were unable to compete with British and Norwegian steam trawlers. In 1931, only about 3,000 tons of Icelandic cod were caught.

Since that year there has been a revival, owing to the increase in the number of French steam trawlers built at Havre or in some cases at British dockyards. They are owned by companies such as *La Morue francaise* or *Pecheries de France*. Stationed at Fecamp and Boulogne, these vessels are from 550 to 1,350 gross tonnage, have a bunker capacity of 250 tons, and a storage space of about 750 cu.m. They leave port at the beginning of February, fish to the south and west of Iceland, and return in April and May either to France or to Reykjavik. In the latter case the catch is transferred to a carrier ship, and the trawlers, after revictualling and refuelling, proceed to the Grand

Fig; 62. French fishing grounds off western Europe
Based on the *Atlas de France*, Plate 53 (Paris, 1936).

Banks of Newfoundland or to the west coast of Greenland for a second season.

At these fishing grounds they join the small fleet of vessels, including sailing craft such as *terreneuviers* or *trotsmats*, stationed at St Pierre and Miquelon, which are the last remnants of the former American colonial empire of France. The French were the pioneers of the Newfoundland fisheries, and in the seventeenth and eighteenth centuries supplied vast quantities of salt and dried cod to Catholic Europe. Certain fishing rights enjoyed after the Treaty of Utrecht in 1713 were renounced under a convention concluded with Britain in 1904. They are now allowed to fish the banks off the coasts of Newfoundland from Cape St John on the east coast round to Cape Ray in the south-west.

Each vessel carries twelve or more little row-boats or *doris* which leave at dawn with two men. Series of lines each with several hundred baited hooks are laid and marked by buoys; the *doris* then return to the ship and the crews spend the day cleaning and salting the previous day's catch. The livers of the fish are usually packed in barrels, but on the most modern vessels the liver oil is extracted on board; the roes are salted, and the offal is converted into fish manure. In the evening, the *doris* go out again to collect the catch.

Miscellaneous fish. A large amount of miscellaneous fish, known as *poisson frais*, is landed at ports along this coast by small and medium-size trawlers, which put out for six or seven days to fishing grounds in the English Channel, St George's Channel, and the seas south of Ireland. There is no specialization; the boats not only bring in turbot, brill, sole, skate, etc., but also take part in the mackerel or herring fisheries. This provides regular employment throughout the year, although the returns are tied up with fluctuations in demand; a good haul in Lent, for example, will produce higher profits than at other times of the year.

Boulogne (Plate 38) is easily the biggest fishing port in France, both for the weight and value of catch, and also for the total tonnage of its boats (see p. 155). Six docks serve the fishing fleet, but the port facilities are insufficient and expansion of quay space is virtually impossible.* In recent years there have been improvements in facilities for curing, salting, and packing, and fast night trains of refrigerator cars provide a good service with the Paris markets. Over 5,000 people, or about

* Details of the facilities (docks, quays, sidings, etc.) at the larger ports mentioned in this chapter are given in chapters 1, 11 and in of volume iv of this Handbook.

one-tenth of the population of the town, find occupation in the activities associated with fish curing, etc.

Dieppe. Although Dieppe handles only about a quarter of the tonnage of Boulogne, it is an important port for the smaller trawlers which fish for *poisson frais*, returning daily to supply the markets. These boats use the outer port (apart from the packet quay) and the Bassin Duquesne. A large covered fish market, with modern equipment and adjacent railway sidings, has been built on the He de Pollet, near the oiler port, and less than four hours elapse between the docking of the fishing boats and the loading of washed fish into refrigerator cars. Sometimes as much as 200 metric tons of fish arrives in the harbour between 1500 and 2100 hours and leaves before midnight for Paris, either in one of the seven daily fish trains or in refrigerator vans coupled on to a Paris boat train.

Fecamp. Geographical conditions are against the development of Fecamp, as the port is naturally poor, and the lines of communication with Paris are unsatisfactory. Yet it is the fourth fishing port of France in value of catch, because it is the chief centre for the fitting out of the big Newfoundland trawlers, and it has the largest single dried cod market in the country. It takes part also in the mackerel and herring industries.

Gravelines has long since lost the importance of days when it shared, with Paimpol, the Icelandic fishing industry. It now has only a few small boats which fish near the coasts.

NORMANDY AND NORTH BRITTANY

While the northern and southern coasts of Brittany are physiographically very similar, there are considerable differences in their respective fishing industries. On the north coast, fishing is represented by the remnants of a once flourishing deep-sea industry, together with part-time coastal fishing that ekes out the meagre resources of the land. On the south coast there are important sardine and tunny fishing centres. In many of the innumerable tidal creeks along both coasts is a little fishing village, and almost all the population gain a large part of their living from the sea. As a result, Brittany has long been the main recruiting centre for the French navy. Nearly one-half of the personnel of the navy are of Breton origin—some 27,000 out of 59,000 in 1935; and about 23,000 out of the 65,000 of the French mercantile marine are also Breton. Some 42,000, or over a half, of the French fishermen are Breton, and of

these about 38,000 live and work in Brittany itself. The rest have migrated to the big trawler ports of Boulogne, Fecamp, etc. In 1933, there were over 8,000 unemployed deep-sea fishermen in the three centres of St Malo, St Servan and Cancale. Large sailing boats decreased to about a quarter of their number before the war of 1914-18, and, moreover, steam trawlers require fewer hands.

Coastal fishing. Along the north coast are numerous small fishing villages, whose population engage in coastal fishing for herring, mackerel, conger, skate, turbot, mullet and crustaceans. Sailing boats, with a multiplicity of types and rigs long adapted to the needs of a locality, are used.. Paimpol, for example, had 272 registered boats in 1937 averaging about 9 metric tons, owned by 272 *patron-proprietaries*; only ninety boats were mechanically propelled. This coastal fishing employs part-time men who also own little farms, and is scattered and unorganized. The collection of shrimps and shell-fish is carried on at low tide by women and children.

Lobsters and oysters have greater commercial importance than the miscellaneous coastal fishing, as they are sent in fluctuating quantities to Billingsgate. But with two exceptions, the industry is in no way comparable with the large-scale enterprises of south Brittany and the Biscay coast. These exceptions are the cultivation of oysters in the Bay of Cancale and at Treguier, and the lobster tanks at Roscoff, where crustaceans caught along the Portuguese and Moroccan coasts are stored.

Seaweed. An associated industry of some interest is the collection of seaweed in the mud-filled inlets. Regulated by ancient custom, the *goemon* and *varech* is cut in spring by men in barges, and is sold to farmers for use as fertilizers, or sent to iodine factories.

St Malo (Plate 39). One exception to this small-scale local fishing is at St Malo, although this port is by no means as important as it was in sailing-ship days. With some 19,000 metric tons of shipping, it is the third fishing port of France, and sends trawlers to Newfoundland waters. About one-quarter of the dried cod landed in France in 1937 came into St Malo.

SOUTH BRITTANY

The water of the Bay of Biscay is considerably warmer than that of the Channel, and so the chief fish landed in south Brittany are sardines and tunny.

Sardines. The French catch of sardines is only exceeded in value

by that of cod. The industry developed between 1870 and 1900 at the numerous small ports along the south coast of Brittany. Fishing is seasonal; it generally starts in February in the Gulf of Gascony and works north to end off Finistere in November, but it is most active in summer. The sailing boats are of 7 to 8 metric tons and have a complement of from seven to twelve men. They leave port after sunset, and begin fishing at sunrise, either directly from the boats, or from small *carots* (dinghies) taken by the larger vessels. The fine-meshed drift-nets (*battude*), about 30 x 9 m., are baited with a mixture of cod roe and pea-nut flour, and are allowed to float vertically in the water. As soon as a haul of about 5,000-6,000 fish has been made, the vessels hurry back to port, where the catch is immediately sold to the factories. The fish are rapidly cleaned and sorted by women, and are then dried and dipped into hot oil. After drying again, they are packed in tins. It is interesting to note that the price of sardines depends not on the fish but on the quality of the oil, the best varieties being preserved in pure olive oil, the cheaper in cotton-seed oil.

Tunny. Fishing for the white tunny (*germon*) is concentrated into a short intense season of some 100 days from the beginning of July to the middle of October. As a result, the fishermen have to find winter employment on Boulogne trawlers, or in coastal fishing, or they may even sign for a short voyage on a merchant ship. The industry began at La Rochelle and Les Sables d'Olonne south of the Loire about 1885, but now some 95 % of the catch is landed at Concarneau, Douarnenez, Groix, Port-Louis and Etel, where the chief factories are situated. The tunny boats of the south Breton coast number about 700, and they are mostly *dundeas* of some 40-60 metric tons. In recent years, however, a larger motorized semi-trawler type has been introduced which can be used for winter fishing. The boats, each with a crew of six or seven, are away from 10 to 15 days at a time, and make from six to eight voyages in a season. Long rods or *tangons*, which can be raised or lowered, are fixed to the base of the mast; each rod has six or seven strong hemp lines and hooks baited with horse hair, maize straw, etc. Fishing is best done on a grey day with nearly calm seas, and the boat sails at about 6 knots with the bait leaping about on the surface. When a fish is hooked, it is hauled aboard, killed, cleaned and hung up by the head on trestles. The boats return at intervals to the port, where the fish is auctioned before unloading, and then delivered to the factories along the quays. The whole catch is preserved, and 172 canning factories are found along this coast, out of a French total of 207. Some of

these factories, however, handle both tunny and sardines. The work is done chiefly by women, who work very irregularly, and are paid by the hour. At Concarneau, for example, 2,000 women are employed on a temporary basis (Plate 40). The tunny is largely sent to Latin America, Brazil, Belgium, central Europe and Greece.

Miscellaneous fish. Sardines and tunny are the two staple fish, but they are by no means the only ones. From most of the small ports, *dundees* take part in coastal fishing; they sail out each day for a few kilometres from the coast and fish for about 12 hr. From the larger ports, notably Lorient, motorized vessels carry on a variety of fishing. The bigger trawlers of several hundred tons steam out as far as the Grand Sole Bank to the south-west of Ireland, chiefly for hake, skate and eels. Smaller trawlers confine themselves to distances within 25 km. for sole, gurnard, turbot, etc. Mackerel and whiting are fished by line from small boats, or by nets from larger drifters.

Crustaceans and Shell-fish. Lobsters are caught along the south Breton coast, either by *casters* (wicker pots baited with dog-fish), or by large-meshed nets 100 m. long which are dragged along the bottom in water 50 m. deep. The *langouste*, or spiny lobsters, are fished on the coasts of Portugal, Morocco and Mauretania, and the lobster fishers are often away as long as three months. After a successful trip, a boat may return with 7 or 8 kg. of live lobsters. The catch is stored on shore in masonry tanks at Concarneau, Audierne, Mane-meur, Port-Haliguen, etc. Oysters are cultivated in the silted ria of Etel at Auray, at La Trinite near Carnac, and at Carnac itself.

On the south, as on the north coast of Brittany, there are a large number of small ports and sheltered anchorages, each with some hundreds of craft. Apart from Lorient, the two largest fishing ports in the south are Douarnenez and Concarneau, while the naval port of Brest accommodates over a thousand small fishing vessels.

Douarnenez (Plate 41) is notable in that, in 1937, 426 of its 500 boats were mechanized. The port is sheltered by the natural breakwaters of the Pointe du Leide and He Tristan, and consists of three parts: on the west is the small fishing port of Treboul almost enclosed by He Tristan, on the ria estuary of Pouldavid is the commercial harbour of Port-Rhu; which supplies the fishing fleet with coal, wine, bait, food, salt, etc.; while the real fishing harbour is in the extremely busy Grand-Port, with its sardine factories and railway sidings. Douarnenez is probably the most prosperous fishing port in France, as it has three distinct fishing flotillas—250 sardine boats, eighty large tunny boats and thirty lobster boats, and in addition to these

some hundreds of boats are engaged in the coastal fisheries. There are twenty-four fish-preserving factories, most of them with modern equipment; women supply the labour, which is specialized and well paid, but intermittent.

Concarneau (Plate 42). This provides a safe anchorage that can accommodate over 1,000 vessels. It also has twenty-four fish-preserving factories.

Lorient is very different from its neighbours; a modern port has been constructed to handle a large amount of fish. Until 1927, the *avant-port* was used by the fishing boats, but between 1920 and 1927 two docks for fishing boats were built by the state. These are the *Grande Bassin* and the *Bassin Long*, and now form the new fish port of Keroman. Dock gates are not necessary, and boats can get in and out at all tides. Colliers are able to berth on the outside of the quays, and adequate coal-storage accommodation with transporter belts enable twenty large trawlers a day to be refuelled. The prompt despatch of fish to market is facilitated by railway sidings and by services of express refrigerator cars. As a result, Lorient has become the second fishing port of France by weight of fish landed, although it is only third by value. Its boats take part in the tunny and sardine fisheries in the Bay of Biscay, in the mackerel and herring fisheries, and in the more distant deep-sea fisheries.

THE BAY OF BISCAY (SOUTH OF THE LOIRE)

The Biscay coast south of the Loire does not offer many natural harbours, and as a result sardine and tunny fishing is on a small scale and is distributed among numerous small villages along the coast.

Oysters. Ideal breeding grounds for oysters are provided by the lagoon coast of the Landes, by the Bassin d'Arcachon (Plate 44), and by the muddy estuaries between Marennes and Les Sables d'Olonne which are sheltered from the westerly gales by the islands of Oleron and Re. Along this coast the Portuguese oyster has largely superseded the European or plate oyster that is cultivated on the English coasts, although the latter has recently increased again in numbers, as shown by the following figures:

<i>Millions of Oysters</i>				
	1911	1920	1926	1937
Portuguese oyster	790	378	1,084	1,230
European oyster	922	463	11	223

Plate 43. Le Croisic (Loire-Inferieure)

Le Croisic is typical of the numerous small fishing ports scattered along the coast. The harbour is situated on the southern shore of the Grand Trait, a large shallow bay.

Plate 44. Oyster pans at Arcachon

The young oysters are placed in these earthenware pans, which are sunk in the shallow lagoon (the Bassin d'Arcachon). It is thus easy to collect the oysters when they attain maturity.

Plate 45. The fishing port at Martigues

Along the Mediterranean coast of France are numerous small ports, sheltering little craft which fish the *etangs* and canals. This example is the St Sebastian Canal at Martigues a cul-de-sac used by fishing boats.

Plate 46. The fishing port at Marseilles

A large number of small fishing boats use the old harbour at the southern end of the port.

The oysters are collected from November to 1 May, and other fishing boats are often laid up during this time because oyster dredging is more profitable. The catch is made for 2 hr. before and after low tide, both men and women taking part, usually in punts. The oysters are cut off from the rocks upon which they grow in large clusters, or are dredged from shallow water. The small ones are sent to the culture beds (*parquets*) at Arcachon, Marennes, Oleron, etc., and the large ones are packed in barrels to send to the Paris market.

Three ports, Les Sables d'Olonne, Marennes, and Arcachon, have over 1,000 registered boats; but most of these are small, and include many oyster punts. *La Rochelle* is the second French fish port by value and fourth by weight of catch. The outer basin of La Rochelle has a fish quay 400 m. long used by a fleet of eighty large steam trawlers, while the smaller fishing boats use the stranding basin. Alongside the fish quay are extensive fish sheds and railway sidings. The neighbouring port of La Pallice accommodates twelve of the largest trawlers, which go to the Newfoundland and south-west Greenland Banks. Smaller trawlers fish for hake, mackerel, herring, etc., while there are extensive coastal fisheries with Diesel and petrol-driven boats, catching turbot, sole, tunny, crab and lobster.

Bordeaux owed much in earlier days to the import of dried cod, and although a large amount (valued at 66 million francs in 1937) is still landed, the item is relatively of small account among the multifarious activities of the great colonial port. There are no special fish docks.

THE MEDITERRANEAN COAST

The fisheries of this coast are much less important than those of the rest of France, but over 9,000 men obtained employment in 1937.

Miscellaneous fishing. The Rhone delta has a large number of little fishing villages. Red tunny, sardines, anchovies, *poisson bleu*, mackerel and skate are caught in the open sea, and a variety of less well-known fish are caught in the lagoons and waterways. The red tunny, much bigger than its Atlantic relative, appears in shoals at the beginning of summer off the coasts of Sicily, Sardinia and southern France. Only 1,800 metric tons of these fish, about a fifth of the total of white tunny, were landed in 1937. It is caught by *madraques*, enormous wide-meshed vertical nets up to 300 m. long, or by *seinches*, a series of nets laid by a number of vessels round and

below a shoal, or by harpoons. The oyster beds at Thau, nearly wiped out by too thorough dragging in 1,907, are carefully conserved.

Some of the fishing methods on this coast are very different from those in other parts of France. The Sete fishers have long boats coupled in pairs (*bateaux boeufs*) behind which they drag a long net with wide wings, an effective method of catching such pelagic fish as sardines and anchovies. Single Catalan boats, or *palavas*, lay drift nets in summer in the open sea, while at all seasons the individual fisherman and his family work in the *etangs*, catching fish by harpoon or by series of complicated fixed nets (*esturies*, *triangles*, and *trabaques*). Nomadic fishermen camp in summer on the coast between Sète and Agde for the special seasonal fishing. People from towns outside the delta, and even from Italy, come every summer to Thau for the shell-fisheries, working until they leave for the wine harvest in Languedoc and the Rhone Valley.

The two most notable of the Mediterranean ports of France are Marseilles and Toulon. There is no special provision, however, for the fishing industry at *Marseilles*, and only about 4,000 tons of fish were landed in 1937—a very small part of the trade of that great port. The 700 registered fishing vessels are mainly small craft of about 2 tons which share the Outer Port with pleasure craft (Plate 46). Although *Toulon* has over 800 small craft, it landed barely 1,000 tons in 1937. *Site*, situated to the west of the Rhone delta, has more boats than any other fishing port in France, but they average less than 3 metric tons each.

ORGANIZATION AND RESEARCH

The government department responsible for the administration of the fishing industry, for the registration of boats, fishermen and catch, and for the compilation and publication of statistics, is the *Ministre de la Marine Marchande*. Scientific aspects of the industry are controlled by the *Office Scientifique et Technique des Peches Maritimes*. Powerful local organizations, such as the *Societe du Port de Peche de Lorient*, superintend to a large extent the activities at the various ports.

Research is carried on at over twenty marine biological stations round the coast. The *Office Scientifique* maintains a laboratory at Paris and at St Servan, a large *Laboratoire de Biologie appliquee a la Peche* at La Rochelle, and numerous smaller stations at many of the ports. Special interest is taken in oyster culture; the *Office Scientifique* maintains the *Inspection Generale du Controle Sanitaire Ostreicole* at

Paris, and there are research stations at Auray, La Rochelle, La Tremblade and Arcachon. Other marine biological laboratories are maintained by (1) the *Ministere de l'Education Nationale* at Wimereux, Luc-sur-Mer, Dinard, Biarritz, etc., (2) by the universities, notably the one maintained by the Sorbonne at Roscoff, and (3) by various public and private societies and institutions. An example of the last is the famous *Institut Oceanographique*, maintained by the Principality of Monaco. France assists international fishery research through her membership of the *Conseil Permanent International pour l'exploration de la Mer* at Charlottenlund in Denmark.

BIBLIOGRAPHICAL NOTE

(1) Detailed statistics are given in the annual official publication, *Statistique Annuelle des Peches Maritimes*, edited and published by the 'Ministre de la Marine Marchande' (Paris). Summary and retrospective tables are given in the *Statistique Annuaire* (Paris). Summaries are also conveniently given in the *Bulletin Statistique des Peches Maritimes des pays du nord et de l'ouest de l'Europe* (Copenhagen), published annually by 'Le Conseil Permanent International pour l'exploration de la Mer'.

(2) The 'Office Scientifique et Technique des Peches Maritimes' publishes the quarterly *Revue des Travaux de l'Office des Peches Maritimes*, which contains valuable articles on many aspects of the fishing and allied industries. It also publishes periodically numerous *Notes et Rapports*, and also a series of *Memoirs* which consist of statistical surveys, summaries of recent research, etc.

Chapter V

MINING AND INDUSTRY

Introduction: Industrial Regions: Coal: Iron Mining and the Iron and Steel Industry: Shipbuilding: Locomotives: Aircraft: Non-ferrous Metals: Electricity: Chemical and Allied Industries: Textiles: Miscellaneous Industries: The Vichy Regime: Bibliographical Note

INTRODUCTION

The first steam engine in France was erected at Le Creusot in 1790, and it was only in the last decade of the eighteenth century that France began to emerge from an elementary stage of industrialization. The state had turned its attention to the fostering of industry and was encouraging the Leblanc process of manufacturing soda; beet-sugar refining industries were set going, new sources of saltpetre had been found, and bleaching by the use of chlorine had been developed. In addition, schools of engineering and industrial science had been set up. The stage was set, but although during the following half-century most of the industries of France were remodelled, there was no spectacular change such as was witnessed in England and later in Germany. Progress was almost imperceptible. St Etienne and Roubaix were the only two towns that increased in size with any rapidity during that period. The two main brakes on the spread of mechanization were cheapness of labour and lack of coal. The oldest colliery in the northern field, that of Anzin, was not opened before 1720, the steam pump was not introduced until 1734, and there was no serious exploitation of coal till 1850. True, the output had doubled between 1828 and 1847, but production in the latter year was only about 5 million tons, whilst consumption about that time, though greater, was only 7½ millions.

In the iron and steel industry, the works on the edges of the Central Massif—Le Creusot, Fourchambault, Montluçon and Decazeville—were still the most important, and as late as 1846, three-fifths of the iron smelting was still carried on in small and primitive charcoal furnaces. Of steam engines there were fewer than a score in use in 1815, and even by 1850 only 5,200 were in use as against 22,500 water mills of various kinds. Even in the textile industry, which developed far more quickly, there were two water mills for every steam mill as

late as 1848. Lille had started the first steam spinning mill in 1801. In 1803 the flying shuttle was introduced into Alsace. This was the pioneer area of modern French textiles, and it experienced something approaching an industrial revolution in the first half of the century.

The disaster of the Franco-Prussian war fell upon France before her heavy industries had been established upon a firm basis. The loss of the Lorraine ironfields with their nascent industries and of the well-established textile industries of Alsace was a great blow. Nevertheless, after 1872 France set out resolutely on the road to recovery. Road, rail and canal construction under state encouragement went on apace. The successful search for the continuation of the Lorraine ironfield on the French side of the new frontier gave to France a share in the advantage of the newly invented Gilchrist-Thomas process which enabled phosphoric ores to be used for steel making. Nevertheless, progress was not rapid.

It was only with the opening of the twentieth century that the forward movement began to be marked. Between 1900 and 1913 industrial activity increased greatly. Then came the war of 1914-18, which put a stop to normal progress, but stimulated invention. There followed a period of reconstruction during which the devastated areas were rebuilt and re-equipped. This gave an opportunity for the closing of small uneconomical units, for amalgamations, for the rebuilding of factories on modern lines with modern equipment, and for the development of housing schemes to accommodate miners and other workers.

The return of Alsace and Lorraine and the control for fifteen years of the Saar coal-mining territory meant, for France, not only the possession of the largest and most easily worked ironfields of Europe, but the acquisition of a highly equipped, modern heavy metallurgical industry, as well as an important and specialized group of textile manufactures. France saw her industrial potentialities vastly improved, and the stimulus of a new orientation was beneficial to her status as a manufacturing country. Many difficulties were, of course, consequent upon this reorientation, not the least being the problem of finding new markets; for the German market organization, except for certain international iron and steel firms, was not acquired with the restored territory. Moreover, welcome as the additional coal supply of the Saar might be, without the access to Ruhr coal in exchange for iron, which the Germans had organized, France was still heavily handicapped by lack of metallurgical coke and by difficulties of communication between Lorraine and the **northern**

coalfields. In fact, Germany lost more than France gained by the separation of Lorraine from the Ruhr.

The period of reconstruction, absorption and re-orientation during which France consolidated her position among the great manufacturing countries of the world, lasted until 1929, when the world economic depression set in. In this crisis, the well-balanced position of the country between large-scale and small-scale industries and the weight of her still important and almost self-sufficing agricultural activities saved France from catastrophe.

By 1936 recovery became marked, but not in time to stem the constantly recurring labour unrest, manifested by repeated strikes; nor to avert the attempt at conciliation by the granting of a 40 hr. week, the result of which was a distinct decline in industrial production. Rearmament, however, set the wheels of industry revolving again with a rapidly increasing tempo. This acceleration continued until the collapse of May 1940.

In all this story of spasmodic industrial development, France has lagged far behind her neighbours. This slow progress is best explained by a consideration of the most outstanding characteristic of French industrial activity—the persistence of a *petit-bourgeois* attitude among the organizers and of the peasant attitude among the workers of France. The preservation and adaptation of the individual skill of the peasant craftsman displayed in small factory and cottage industries and the canalization of this specialized but cheap labour in the service of large markets, has been the outstanding feature of the great French luxury industries; and although it has called for a high degree of intelligent organization and co-operation, it has militated against concentration. This has been particularly marked in the textile activities of the Lyons area and indeed in the bulk of French industry, other than that which is concentrated on the coal- and ironfields. Yet it is in the nature of things that this loosely knit but highly efficient method of production should eventually give way to concentration of effort and mass production, as competition becomes fiercer and improved communications encourage and facilitate migration of the worker to the larger towns.

To sum up: The peripheral situation of the major iron- and coal-fields of the country and the inadequate supplies of coal and metallurgical coke have resulted in a slow pace of industrialization, in the continued quasi-self-sufficiency of French agriculture, and in the survival of many small-scale but highly specialized industries to supply the world's luxury markets.

As an index of the relative importance of the various industrial occupations in France, the following table is appended, giving the number of people employed in each of the main branches of industry; for comparative purposes and for completeness the non-industrial occupations are also included.

Industrial and other Occupations in France', 1931

Occupation	No. of persons employed	Occupation	No. of persons employed
Fishing	66,747	Textiles:	920,460
Forestry	58,447	Cotton, spinning and weaving	192,036
Agriculture	7,578,986	Wool, spinning and weaving	167,467
Mining	366,948	Silk	123,085
Quarrying	73,729	Hosiery	120,199
Food industries	541,671	Lace	90,224
Chemicals	238,297	Linen, hemp, jute	99,987
Rubber	63,124	Bleaching and dyeing	67,681
Paper and cardboard	103,281	Clothing	1,001,136
Printing, etc.	154,819	Leather, shoes, gloves	299,923
Ferrous metallurgy	147,034	Wood-working	649,270
Non-ferrous metallurgy	26,197	Transport	811,298
Engineering:	1,436,612	General commerce	2,329,219
Forging, edge-tools, wire	06,441	Banking, insurance	288,983
Mechanical engineering	80,131	Professions	657,757
Electrical engineering	50,409	Domestic and personal service	893,376
Building construction, etc	886,138	Public services	1,313,415
Cement, bricks, pottery, glass	223,095	Total occupied population	21,611,835

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

INDUSTRIAL REGIONS

Figs. 63 and 64 show respectively by departments the percentage of the working population engaged in industry and the amount of steam power employed in driving machinery. Viewed in conjunction with Figs. 70, 83 and 81, showing iron and steel production, number of textile workers and consumption of electricity in chemical and metallurgical industries, these maps provide a broadly accurate picture of the distribution and relative importance of the major industries of France. Five dominant industrial areas stand out: (1) the northern region, comprising the two departments of Nord and Pas-de-Calais; (2) the eastern region, including Lorraine and Alsace; (3) the region of the Centre, whose boundaries are less well defined, but whose nucleus lies in the departments of Rhone and Loire. This area sends tentacles into the northern Alps (Grenoble area) and into the southern Jura;

(4) the region of the Garonne basin, including the Pyrenees, with control centres in Toulouse and Bordeaux. This is defined in Fig. 81, showing electrical energy consumed in chemical and metallurgical work; (5) the metropolitan area of Paris, the industrial importance of which is indicated by a remarkably high consumption of steam power in factories.

Fig. 63. Percentage of working population engaged in industry, by departments, 1936

Based on *Recensement general*, 1936, vol. 1 (Paris, 1938).

Apart from these main industrial regions there are very many isolated industrial towns such as Troyes and Reims carrying on specialized work of considerable importance—survivals of provincial independence.

The northern region is paramount, the main locating factor being, of course, the coalfield. The two departments of Nord and Pas-de-Calais produced, in 1938, 28 out of the 46 million tons of coal mined in France, 1 million out of the 8 million tons of pig-iron, and 1½ out of the 5 million tons of steel. Furthermore, the region is one of the chief textile centres, having 2·8 out of the 8 million, ordinary cotton

spindles of France and employing some 200,000 textile workers in the department of Nord alone.

The industrialization of the *eastern region* is based for the most part, not on local coal, although the Saar basin has had some influence on its development, but on the presence of the important

Fig. 64. Steam power in industry, 1936, by departments

Based on *Annuaire Statistique*, 1938, pp. 109-10 (Paris, 1939).

Squares proportional in area to developed power. In some areas (e.g. Paris, Lorraine, Pas-de-Calais and Le Creusot), where there are many very large power-producing plants, the average power of the individual prime mover (i.e. steam engine) is high; in other districts (e.g. lower Seine, Nord, St Etienne), where there are numerous small-powered engines driving the machinery of small textile or light engineering factories, the average power is much lower.

minette iron ores of Lorraine. The output of ore in 1913 amounted to about 43 million tons; after the war of 1914-18 it rose to a maximum in 1929 of over 50 million. The ore from this field constitutes roughly 90 % of the national production. About half the output is consumed in the iron and steel industries. This region

employs as many iron and steel workers as the north, but is concerned mainly with the production of pig-iron, of which its output in 1937 was 6'2 million tons, as compared with only 1 million in the north. The textile industry of the east was based on the water power, soft-water supplies and skilled domestic textile labour available in the valleys on the flanks of the Vosges—the eastern valleys in Alsace, the southern valleys in the Belfort district, and the western valleys in Lorraine. The area includes also the slopes of the northern Jura. The industries of these groups of valleys have between them 5 million cotton spindles and employ some 116,000 workers in the textile industry with all its branches.

The metallurgical industries of the *Centre* are based on the small coalfields of the eastern Central Massif, but they also rely, to a certain extent, upon coal imported into the district, and wholly on ore and metal from other areas. The district only employs one-fourteenth of the labour devoted to metallurgy in France, but is important because it includes the principal armaments works of the country, at Le Creusot and St Etienne. The engineering industry is, to a certain extent, centralized in Lyons, but light metallurgical work, dependent on the electric furnace, is located in the Alps and the Central Massif. The centre of textile manufacture is Lyons, but the industry occurs over a wide area—in the eastern uplands of the Central Massif, in the southern Jura, and in the northern Alps as well as in the Rhone valley. In 1931 the silk and rayon industry employed about 123,000 persons. Power is obtained from the small coalfields of the region, and, to an increasing extent, in the form of electric current generated from the torrents of the Alps, the Jura and the Central Massif. The raw material for the silk industry is now for the most part imported from the Far East via Marseilles. Smaller quantities come from Syria and Italy.

A south-eastern sub-region centres in Grenoble. Here again, modern development is clearly allied to the exploitation of hydro-electric power. Powerful glacier-fed torrents and glaciated valleys with abrupt breaks of slope are the geographical conditions underlying this development. Conditions favouring the generation of hydro-electricity are not conducive to accessibility and ease of communications. Hence raw materials must be light. On the other hand, the electric furnace is necessary for the production of aluminium and of certain types of steel and ferro-alloys and for electro-chemical work. The majority of French aluminium works are situated in the Alpine valleys, Small-scale industry, thanks to electric power and a

certain amount of state encouragement, has penetrated into the heart of the Alps, in the upper valleys of Isere and Arc, but the more important industrial groups are found in the broad vale of Gressivaudan that lies between Grenoble and Chambery. Glove factories, cement works, engineering shops, silk and rayon factories line the edges of the plain. There are no less than 357 silk-weaving establishments in the department of Isere alone. Thus the industrial sub-area of Grenoble overlaps, to a considerable extent, that around Lyons.

The south-west, or Pyrenean region, looks mainly towards Toulouse, but has a western focus in Bordeaux. As in the Alps, economic development has accompanied the utilization for electric power of the mountain torrents. Apart from a little mining of iron and silver-lead-zinc ores and of some of the rare metals, activities are concerned with electro-metallurgical and electro-chemical work. Electrical energy is also supplied to Toulouse, where an important nitrate plant has been established. Though the Pyrenean industrial activities come a very long way behind those of Lyons and Grenoble, the two regions have much in common. Power is supplied from the upper basins of the Adour, Ariege and Tet to the railways and industries. The quarrying of building stone and of limestone for cement, the mining and reduction of bauxite, iron mining and a little steel production are the chief of the mountain industrial activities. In Bordeaux and Toulouse there are leather and skin industries; whilst the manufacture of superphosphates, of explosives and recently of aeroplanes has reached some importance.

Greater Paris is the largest manufacturing region in France, its population of 6 millions providing both a reservoir of labour and a market. The luxury industries, with which it is popularly associated—such as fashion goods, fabrics, jewellery and glass-ware, *objets d'art*, etc.—are of relatively minor importance. Besides these and the usual 'metropolitan' industries—printing, food production, textiles, furniture-making, public works contracting—many others are highly developed, especially the metal-using industries. All the important motor-car factories of France, save one, are found here, many of the aircraft factories, and electrical and light metal industries in great variety (see Fig. 35). The heavy industries, moreover, are also considerable: St Denis is one of the two most important centres in France for marine engineering, and the construction of heavy electrical equipment, factory machinery, barges and small craft, together with the manufacture and repair of rolling stock, all have important centres in the region (see Fig. 36).

Electric power is derived mainly from hydro-electric generating plants in the Central Massif, but the Paris region has six large thermal-electric stations (see Fig. 78) which supplement the current output as and when required. Large quantities of coal are consumed by individual factories, and the gas works also play an important part in industry. In 1936 the department of Seine produced nearly 650 million cu.m. of gas—40% of the entire French production—and nearly 700,000 tons of gas coke. The power stations and gas works, like the heavier industries, lie mainly downstream at St Ouen and beyond Gennevilliers in the river loop, and upstream at Ivry and Vitry, with minor groups in the central section of the river around Issy, so as to secure adequate supplies of water, cheap water transport for coal imports, and ample building space in the low ground of the river flood-plain, which is in any case less desirable for residential sites.

While the best known products of Parisian industry are made in small workshops, the bulk of the industrial output comes from larger establishments; the distribution of the factories is shown in Fig. 34. They lie in a belt of varying width which almost encircles the nineteenth-century city except where the Bois de Boulogne, to the west, forms a non-industrial gap. As far as transport facilities are concerned, the river, railways and roads seem to have offered more attractive locations for industry than the canals, except along the northern end of the St Denis Canal. The heaviest metal industries lie near the river at St Denis, Gennevilliers and farther downstream, though there is a subsidiary centre above the Marne confluence, and an important centre at Corneuve and Le Bourget, along the Nord railway leading to Laon. The electrical, motor-car and aircraft industries, the latest to develop, have a pronounced westward location towards the river at Suresnes and Courbevoie with an isolated group in the south-west bend of the great loop at Boulogne-Billancourt. In the earlier development of factories, within the limits of the fortifications, the general metal industries concentrated in the south-west and in the north-east, but in their later development in the suburbs they kept almost entirely to the north and north-east (cf. Figs. 35 and 36). The construction of ships, barges, dredgers, tugs, etc. has two centres—from St Denis downstream to Bezons, and upstream beyond the Marne confluence. Textiles have, in general, an eastward location; heavy chemicals are mainly concentrated at St Denis, but the manufacture of soap, photographic and pharmaceutical materials is fairly widespread; the tanning industry is concentrated along the Bievre river.

In the present century the greatest expansion has been westwards and downstream, with subsidiary movements to the north-east towards Le Bourget and south-eastwards beyond the Marne confluence. Recent years have seen a continuation of these tendencies with the establishment of the Ford factory at Poissy, just below the Oise confluence, and aircraft works at Colombes, Sartrouville and Les Mureaux. There has been expansion, too, in the district from Choisy to Villeneuve-St Georges above the Marne confluence, and along the main Orleans and P. L. M. railway lines. At Champagne-sur-Seine, for example, there is a new factory for the manufacture of electrical equipment covering 32 ha. In general, however, the expanding industry of the Paris region is attracted not south-eastwards towards the heart of the country, but north-westwards towards the lower Seine, the ports of Havre and Rouen, and the canals leading to the northern coalfield.

COAL

France has always been deficient in coal. The average production for the years 1932-8 was about 46 million tons, whilst the average consumption for the same period was 71 million tons. The following tables give some details of production and consumption.

The Northern Coalfield

France has only one large coalfield. It lies in the departments of Nord and Pas-de-Calais, and is a continuation of the Belgian field that skirts the northern edge of the Ardennes. The French part of the field is worked in a long curving belt at the foot of the chalk ridge of Artois from the neighbourhood of Aire to the Belgian

frontier (Fig. 66). The coal lies beneath a hidden upfold of chalk overlain by soft, sandy deposits which rise slightly above the Flanders plain to form the Pevele and Gohelle districts. The deep-seated strata have been greatly disturbed by faulting and overthrusting and the coal measures have been folded over upon themselves in the southern part of the basin, so that they lie, in places, beneath sedimentary rocks of an earlier age. The coal zone is divided by faults into a series of sub-basins, besides which faulting has frequently interrupted and displaced the seams. This makes mining difficult and expensive. The French part of the coalfield covers about 51,000 ha. and forms a narrow belt about 100 km. long and 5-15 km. wide. From the Belgian frontier it passes west-south-west through Valenciennes towards Douai and then turns west-north-west through Lens and Bruay. It ceases to be worked beyond Ftechinelle, just south of Aire, but its presence has been proved in the Boulonnais, suggesting a continuation of the deposits in the direction of Kent.

Fig. 65. Above: distribution of coal and lignite fields, with 1936 production figures. Below: output in 1936 by departments

Based on *Statistique de L'Industrie Mine'rale*, 1936 (Paris, 1938).

There are many thin seams, some of them less than 0.4 m. thick, the average being about 1 m., and mining is carried on at depths exceeding 900 m., the average being 400 m. In parts of the Nord department the seams dip at an angle of 40° . Mining is easier in the Courrières-Lens-Grenay district of Pas-de-Calais, where the strata

Fig. 66. The northern coalfield. Above: distribution of collieries in relation to navigable waterways. Below: distribution of coke ovens, iron, steel and engineering industries in relation to railways (see also Plates 47, 48 and Fig. 73)

Based on the *Carte Industrielle* and the 1 : 25,000 maps forming G.S.G.S. series 4041.

dip less steeply and where there are some thick seams. Intervening barren rocks divide the field into two sections—that of Valenciennes in the east and that of Lens in the west. The quality and type of coal varies greatly in different parts of the field and even in the same district (cf. table on p. 180). For example, at Aniche coal of highly volatile composition occurs in the upper seams while **hard** anthracite is **mined at greater** depths.

During the war of 1914-18 the mining area suffered great damage by shelling and through the flooding of the mines by the Germans in 1915-16. In the 10 years succeeding the war the district was restored, the mines re-equipped on modern lines and their productive capacity improved. Since then mining methods have continued to make progress. The amount broken down with the pneumatic pick-hammer in Pas-de-Calais increased from 86.3% of the output in 1929 to 92% in 1936. In 1913 the percentage had been only 47. In the Nord department mechanical extraction reached 99.1% in 1936, but dropped to 97.8% in 1937. Between 6,000 and 9,000 pneumatic drills are used, and there are over 1,500 km. of pipes to carry compressed air to the coal faces. Coal mining is in the hands of a dozen large firms and several smaller ones. Eight of the large companies have an annual output of between 2 and 4 million tons each.

The making of *metallurgical coke* (Figs. 66, 67) takes place at many points on the coalfield, particularly in the Lens (Pas-de-Calais) section, which has about 1,500 out of a total of 2,500 coke ovens. In this western part, almost all the coke output is from local coal, but in the east there are a number of large installations, set up for the most part since 1918, which use in addition Belgian, German and Dutch coal. About one-half of the French output of metallurgical coke (which amounts to about 5 million tons a year) is made in the pithead cokeries of the northern coalfield, the location of which is indicated on Fig. 66. The output of gas from these cokeries in 1936 amounted to 1,327 million cu.m., most of which was used directly in the mining, metallurgical and chemical industries or for the generation of electricity. Apart from gas, the chemical by-products of coking have been rapidly increasing in importance, and now far outweigh in value the gas and coke produced (see below, p. 224).

In comparison with that of metallurgical coke and gas produced from coke ovens, the output of coal-gas and gas-coke from retorts at gas works is small—only 42,000 tons of coke and 35 million cu.m. of gas in 1936. A gas grid, similar to those of Belgium and the Ruhr, for the pooling and distribution of coke-oven gas and coal-gas, has been established. It covers a large part of northern France, the main centres being Bethune, Douai, Lille and Valenciennes.

The manufacture of *patent fuels* affords an economic means of using up coal dust and waste, which is mixed with pitch derived from tar distillation, or imported. It is carried on at Aniche, Ostricourt, Anzin, Bruay, Nœux-les-Mines (see Plate 47) and Courrières. Briquette making (10 kg. blocks of fuel used on railways and ships)

Plate 47. Coal mining at Noeux (Pas-de-Calais)

The installation comprises the pit-head, shale-heaps, a briquette factory and extensive railway sidings, in a setting of cultivated fields.

Plate 48. Iron and steel works at Escaudin (Nord)

This modern works lies just west of Denain (see Fig. 66). In the centre is a group of four blast furnaces; to the right, steelworks and gas-holder; in the distance, beyond a stretch of arable fields, a 'garden city' on the outskirts of the old village.

Plate 49. Coal mine at Mericourt (Pas-de-Calais)

A comparatively small mine (compare Plate 47), but none the less typical, with pithead gear, dumps of pit-props, railway sidings and a modern workers' village of houses with gardens—known in this case as 'cité du Maroc.' The mine lies about 4 km. south-east of Lens.

Plate 50. 'Cites ouvrières' near Lens

A 'garden city' built for miners by a colliery company—a considerable advance on the crowded urban industrialism of the nineteenth century.

and the making of 'ovoids' for domestic stoves have attained considerable importance. Nearly three-quarters of France's patent fuel production, which amounts to 8 million tons, comes from works attached to coal mines, and of this, in 1936, 57.5 % (nearly 37 million tons) came from the northern coalfield. Aniche produced the bulk of the briquettes.

Fig. 67. Output of coke by departments, 1936

Based on *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

Squares proportional in area to output. In general, metallurgical coke, i.e. for use in blast furnaces and in certain other operations in iron and steel manufacture, is produced in batteries of ovens, either at the pithead in coal-mining areas or adjacent to smelting works. Gas coke, used domestically and in factories for heating and the raising of steam, is a by-product of the manufacture in retorts of ordinary coal-gas by gas works. Metallurgical coke is much harder and less frangible than gas coke: it has to withstand the heavy burden of ore in the blast furnace.

In the modernized collieries of this coalfield the output is now used to the utmost: new methods of washing and screening ensure

the maintenance of an even grading of the coal and the efficient collection of dust, whilst patent fuel making, coking, the making of tar products and finally the hydrogenation of coal to produce fuel oil are ancillary industries (see pp. 224-5). The reconstruction of the devastated coalfield area after 1918 made possible a great improvement in the housing of the mine workers, and the older, rather drab rows of gardenless cottages ('corons') have given way to 'cites' or 'garden villages' of separate houses, each with its own garden, laid out in rectangular or other geometrical patterns (see Fig. 73 and Plates 49 and 50).

The Eastern Coalfield

The Saar coalfield, handed back to Germany in March 1935, extends beneath the frontier into the French department of Moselle in Lorraine (see Fig. 71). Coal is mined in the valley of the Rosselle, a left-bank tributary of the Saar, and in the small valleys of the Merle and the Bisten. Farther west the coal measures lie too deep for exploitation, but faulting brings them to within 790 m. of the surface at Pont-i-Mousson on the Moselle. It is not yet mined here, but its presence beneath the iron ores of the district may one day be an important factor in the development of the Lorraine iron industry. Modern improvements in the technique of deep mining, however, have made possible a small westward extension of the Lorraine field. During the 15 years in which France controlled the Saar mining interests, this Moselle section of the field was vigorously exploited: the Germans even accused the French of extending their galleries across the frontier into Saar territory. Be that as it may, output of coal in Moselle increased from 379 million tons in 1913 to 67 million tons in 1938, and has provided a valuable contribution since 1935 to France's depleted resources. The quality of the seams improves on the whole with increasing depth. The Petite-Rosselle mines have a seam 3'4 m. thick and produce coal of good quality. The La Houve mines give only poor-quality coal, but this is utilized at the pithead for the generation of electric current. The deep mines of Hopital and Merlebach are worked by German iron and steel firms.

Saar coal, unfortunately, does not lend itself satisfactorily to the production of metallurgical coke without the admixture of other coal (cf. table on p. 180), so that the steel industries of the Saar territory depended largely on coal and coke imported from Westphalia. Nor is the utilization of coal for by-products very far advanced, but the use of small coal in the generation of electricity is important.

Coalfields of the Central Massif (Fig. 68)

The coal measures of the Central Massif are seamed with valleys following the original lines of folding and faulting, a condition which has greatly assisted mining and communications and therefore industrial development. Good examples are afforded by the line of depression that leads from the Rhone valley to the Loire along the St Etienne coalfield between Givors and Firminy, and that in which the Blanzky-Montceau-les-Mines mines occur in the Le Creusot district. This natural passage-way is followed by two main roads, a railway and the Centre Canal (cf. p. 205).

The Blanzky concessions employ about 9,000 workers and produce about 2 million tons of coal a year, as well as 300,000 tons of patent fuel. The Autun section of the Epinac field, a little farther north-west, produces in addition about 100,000 tons a year of oil shale, which is distilled locally.

The St Etienne field in the department of Loire had an output of 3-24 million tons in 1936 (Plate 51). Some of the coal makes good metallurgical coke, which is used locally (cf. p. 204). In 1936, 372,000 tons of coke were produced from 233 ovens at the collieries of St Etienne, Roche-la-Moliere and Firminy, together with the usual chemical by-products. Much of the rest of the coal is gas-coal, and gas is manufactured and distributed over a wide area. Some is used in the generating of electricity. The small anthracite field of Roanne is also in the department of Loire.

Farther south in Gard, at the foot of the Cevennes, the Ales coalfield with the mines of Grand-Combe and Barrage produce some 2 million tons of high-quality coal. About one-half of the output is used for the manufacture of patent fuel, in the production of which the department of Gard ranks second to that of Nord. The rest is mainly consumed by the local metallurgical industries.

From north to south, through the centre of the Massif, runs a line of faulting along which small coal basins are strung out. The Decize mines in Nièvre on the northern edge of the Massif encouraged the establishment of a small specialized steel industry, as also did those of Commentry. This last only produces half a million tons, but is useful to the industries of Montluçon. In Puy-de-Dôme the engineering and other industries of Clermont-Ferrand receive coal from the small basin of St Eloi, in the 'coal furrow', and Brioude and Brassac in a small upland basin in Haute-Loire also contribute small quantities.

Fig. 68. Coalfields and industrial centres of the Central Massif
 Coalfields stippled; chief railways are shown (double-track thick lines, single-track thin lines); the main hydro-electric power stations are indicated by crosses (cf. Fig. 78); R.G. Rive de Gier; S.C. St Chamond; F. Firminy. The industrial centres are referred to in the paragraphs on iron and steel and textiles (pp. 204-5, 236 and 239).

The two most important fields of the western part of the Massif lie in the river basins of the Lot and Tarn. The Aubin mines near Decazeville produce over half a million tons; they supply the armaments works of Tulle and the metallurgical works of Villefranche-de-Rouergue, Decazeville, and Viviez. The Carmaux-Albi collieries produce just under a million tons for the railways that focus in this district, for the steel works of St Juery and for the woollen industries and foundries of Castres and Mazamet. The Graissesac collieries have developed rapidly of late, and produced 200,000 tons in 1936.

Lignite

French lignite production is small compared with that of Germany, for example—less than 1 million tons as against about 180 millions—and its significance in the national economy is not great (Fig. 65).

Lignite Production, 1936

Region	Department	District	Thousand tons
Provence	Bouches-du-Rhone	Fuveaii	631
	Basses-Alpes	Manosque	79
South-west	Gironde	Hostens	198
Comtat	Gard	Barjac	21
	All other areas		14
		Total	943

There are small deposits in the Cretaceous and Tertiary rocks at numerous places in southern France, particularly in the departments of Herault, Gard and Landes, but the only two worked to any extent are those of Fuveau, north-east of Marseilles in Bouches-du-Rhone, and of Hostens in Gironde; in both cases the output is employed for the most part in the generation of electricity, but the Fuveau lignites are also employed in the production of alumina from the bauxite deposits of Var (cf. p. 213),

IRON MINING AND THE IRON AND STEEL INDUSTRY

The following comparative table illustrates the relative position of France in the coal, iron and steel industries of north-western Europe, the U.S.A., and the rest of the world.

Output of Coal, Iron Ore, Iron and Steel in 1936
{in millions of tons}

Country	Coal and lignite	Iron ore	Pig-iron	Steel
France	46'1	33'3	6'2	67
Great Britain	2285	12'7	7'7	11'8
Belgium	279		3'2	3'2
Luxembourg		49	2'0	2'0
Germany	319'7*	6'6	15'3	19'2
U.S.A.	488'8	486	31'0	47'8
Whole World	1,430-0†	1700	90'2	121'7

161 '3 lignite. † 200'0 lignite.

Four separate groups of industries are involved in what is commonly referred to as the 'Iron and Steel Industry', and the geographical influences on their location are worthy of separate analysis.

(1) The mining of iron ore is clearly' dependent on geological circumstances for its location, but the mode of utilization of the ore varies in accordance with its iron content and the nearness of the field to fuel supplies. Generally speaking a low-grade ore (iron content 20-30 %) will tend to be smelted on the spot because of the high cost of transporting bulky material only one-quarter or one-third of which is actually going to provide useful metal. A high-grade ore, on the other hand (iron content 50-70 %), may more economically be transported to a coalfield for smelting. Thus a large proportion of the lean Lorraine ore is smelted locally, whereas the richer Algerian ores are sent by sea to the ports of France and Britain.

(2) Blast furnaces for smelting iron ore may generally be found in one of three types of situation:

(a) At the source of the fuel, e.g. the northern coalfield and Le Creusot, especially if, as in these two cases, the industry is of long standing, and was based originally on small local ore supplies.

(b) On the ore field, e.g. Lorraine, using coal or coke imported from a distance.

(c) At ports, e.g. Boulogne, the lower Loire, and Boucau (Bayonne), where imported ore and fuel are both available.

(3) The steel-making industry has for its main raw materials iron, either molten or in pig form, and scrap; in 1936 the consumption of scrap was 27 million tons. The industry may therefore be located:

(a) Adjacent to a blast-furnace works, where molten iron from the furnaces can be converted directly, without loss of heat, into steel

(e.g. many works in Lorraine); this is the usual method in the great modern iron and steel works, where, too, the coal is coked on the spot, and power and by-products are derived from coke-oven and blast-furnace gases.

Fig. 69. Graphs showing output of coal, iron ore, pig-iron and steel, 1913, 1920-38

Based on *Annuaire Statistique*, 1938 (Paris 1939).

These graphs form a rough index of French industrial prosperity.

(b) In an engineering area where abundant scrap is available as a 'waste' product of the engineering works which at the same time form an assured local market for the steel output (e.g. St Etienne, the northern coalfield, and Paris).

(c) In an area where hydro-electric power is available for use in special small-capacity furnaces producing mainly high-grade alloy steels (e.g. in the Alpine valleys).

The process of steel making will also vary according to geographical circumstances. Thus an area far from coke supplies will tend to use the Bessemer converter, in which fuel consumption is almost nil, whilst the coalfield engineering regions will use the Siemens open-hearth furnace which uses fuel, but can take a large percentage of scrap. Further, since the bulk of the ores used, whether from Lorraine or Algeria, are phosphoric, basic linings to both converters and open hearths will be employed. So Lorraine makes what the French call 'Thomas' steel (basic Bessemer), the northern coalfield, St Etienne and most of the other centres make 'Martin' steel (basic open hearth). Crucible steel is mainly made in small quantities for special purposes, e.g. the making of armaments, cutlery, etc., and so the manufacture will tend to attach itself to the market for its products. Thus almost the entire French output—which only amounts to 4,000-5,000 tons annually—is made in the St Etienne area and at Le Creusot. Finally, as already mentioned, the regions with water power produce electric steel.

Iron and Steel Production by Variety, 1936 (in thousand tons)

Pig-iron		Steel	
Phosphoric (over 1 % phosphorus)	5,675	Acid Bessemer	39
Semi-phosphoric (0' 12-1-0% phosphorus)	63	Basic Bessemer	4,410
Haematite	329	Acid open hearth	31
Special irons (Spiegel, ferro-manganese, etc)	163	Basic open hearth	1,918
		Crucible	5
		Electric	283
Total	6,230	Total	6,686

The relationship of the various processes and products of the iron and steel industries is illustrated in the annexed table.

(4) The working up of iron and steel into finished products is commonly termed engineering, though this in its widest sense embraces industries which use non-ferrous metals—copper, brass, zinc—as well as iron and steel, and many other diverse raw materials in addition. The location of specialized branches such as shipbuilding and marine engineering, locomotive building, automobile and aircraft manufacture is often traceable to definite geographical factors, whilst general engineering tends to be more ubiquitous in its distribution. Even so, the heavier branches tend to be located in areas where large fuel supplies for power are available, i.e. on the

OH (France HI)

IRON MINING AND THE IRON AND STEEL INDUSTRY

coalfields, where also generally speaking the main metallic raw materials are most easily obtained, whilst the lighter trades show a wider distribution corresponding mainly to the distribution of the major population centres which are their markets. Thus a map showing the location of all industries falling within the term 'engineering' would omit very few important towns in France (Fig. 74).

Iron Ore

Ores of iron are found in small quantities in the sedimentary rocks of most parts of France, and iron working and iron smelting have been carried on sporadically all over the country where wood was available for charcoal and water for the hammers. With the introduction of steam power, the main development of the industry took place on the northern coalfield, but a number of scattered industries survived on or near the small coalfields of the Central Massif, those of Le Creusot and St Etienne for example. To-day the local ores are either worked out or are unprofitable, but the industries based on them continue to exist by importing pig-iron and in some instances also coal. Some of the firms concerned are engaged in making armaments, and their survival, apart from industrial inertia, is due to an avoidance, for strategic reasons, of the frontier coal- and iron-fields. In other instances they have developed special interests, such as the making of crucible steel.

With the development after 1878 of the Gilchrist-Thomas process of steel making, the large-scale utilization of the phosphoric ores of Lorraine became the basis of the iron and steel industry of both France and Germany. The ore resources of France were doubled when she regained the Metz-Thionville portion of the ironfield after the war of 1914-18. The most recent estimate of the reserves puts the total at about 4,500 million tons, of which nearly 4,000 million tons lie in Lorraine, and almost all the remainder in Luxembourg. At the 1927 rate of extraction, it was estimated, exhaustion would be reached in from 60 to 100 years.

The annual production of the French iron mines has fluctuated greatly since the end of the 1914-18 war, in sympathy with the current political and economic situation (Fig. 69). In 1929, the peak year of post-war recovery, a total output of over 50 million tons was reached. The output dropped again, largely as a result of the world depression, but partly because Germany, the chief market for French ore, had turned increasingly to Sweden for supplies. The overwhelming preponderance of the Lorraine fields—Metz-Thionville in

From *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

the Moselle department, Briey, Longwy and Nancy in the department of Meurthe-et-Moselle—is clear from the above table; the last three have regularly contributed about 52% of the total national production, whilst the Metz-Thionville region (in German hands between 1871 and 1918) produced most of the rest (42%).

The only other ironfield of any note is that of Normandy. Though insignificant in comparison with that of Lorraine, it is remarkable for the richness of its ore. In 1929 and again in 1937 its output approached 2 million tons.

The Lorraine Metallurgical Industry

In Lorraine the ore underlies the oolitic limestone plateau of Jurassic rocks between the rivers Meuse and Moselle. The plateau forms a rough triangle, nearly 100 km. long from the Luxembourg frontier to its apex near Nancy and about 40 km. wide in the north. It has a scarped edge facing east and north-east; the ore outcrops along this edge and dips gently west or south-west. The iron deposits lie in the Aalenian series of rocks which are sandwiched between the lower layers of the Middle Jurassic and the upper layers of the Lias and are thus almost exactly equivalent in age to the Northamptonshire ores in Britain. The tributaries of the Moselle traverse the plateau from west to east, trenching deeply as they cross the scarped edge. In these valleys, and along the scarped edge of the plateau, the ore is exposed and can be reached by adits driven into the valley sides (Plate 52). On the northern edge of the plateau the iron beds can even be quarried in a few places. Farther to the west, they dip down and the valleys are not deeply etched, so that the ore is reached only by deep shaft mining.

The most important characteristic of the Lorraine ores is that they are phosphoric and therefore had to wait for the invention of the Gilchrist-Thomas 'basic' process in 1878 for their full exploitation. The upper beds of red, sandy ores are very friable, do not stand transport well and are largely used to mix with other ores; they yield up to 40% of metallic iron. Below these comes the best 'Minette' ore, unfortunately largely worked out. This occurs on the northern edge of the Briey plateau. A less rich, yellow, calcareous ore is found between the valleys of the Algringen and Orne. Below this again and much more widely distributed are grey, calcareous ores, having an iron content of only 38%, but occurring in relatively thick seams, varying from 2 to 6 m. Still deeper lie poor gravelly ores very little worked.

Fig. 70. Output of pig-iron and steel by departments, 1936
Based on *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

Although the ferruginous content of the Lorraine ores is not high, there are compensating factors that make the deposits very valuable. The dip of the strata is gentle and is very little disturbed by folding or faulting, so that mining is not costly, as it is, for example, with the rich Siegerland ores of Germany. The calcareous matrix makes the ores almost or quite self-fluxing, the siliceous ores of the Nancy region being an exception. Again, the Lorraine ores are porous and easily reduced, requiring a relatively small fuel consumption in

Fig. 71. Lorraine in relation to the coalfields and ports of north-western Europe. The main lines of rail and water transport are shown

smelting. The chief disability in the working of the ores is the relatively heavy cost of transport involved in bringing the ore to the fuel, or, conversely, the fuel to the ore. Communications are difficult in every direction (Fig. 71). The journey from the Westphalian coalfield is long and involves a steep ascent from the Rhine valley. Transport to the Franco-Belgian coalfield involves the crossing of the Ardennes. The Saar coalfield, which lies nearest, does not produce metallurgical coke without the addition of Westphalian or other coal. Furthermore, the field lies on the frontier between France

Plate 51. St Etienne

View of an industrial section of the town, with a large coal mine, showing pit-head gear, washing and election power station, and on the right a dump of pit-props; the whole is set on an undulating upland, just over 500 m. above sea level.

Plate 52. Iron mining in Lorraine

Entrance to an adit mine in the Fentsch valley near Hayange (see Fig. 72). The employment of electric haulage is general in the Lorraine mines.

Plate 53. Iron and steel works at Joeuf

The works are situated on a flat terrace in the deep-cut meandering valley of the Orne between Homecourt and Moyeuvre (Fig. 72); the river is in the foreground. In the centre is a group of blast furnaces with their attendant hot-blast stoves; to the right are steel works and rolling mills.

and three foreign countries, and disorganization has followed war three times within living memory.

The Lorraine field is divided by faults and barren ground into four producing areas: that of Nancy in the south, Metz-Thionville in the north-east, both lying near the scarped edge of the plateau of C6tes de Moselle, that of Briey in the broader western part of the plateau itself, and that of Longwy in the north-west, overlapping into Luxembourg.

The Nancy region was the first to be exploited. Mining by adits takes place in the plateau edges overlooking the Moselle and in those of the outlying limestone massif covered by the Bois de Faulx. The ores of this area are unsuited to long-distance transport, for they are sandy and friable and the iron content is relatively low. Moreover, the ore is not self-fluxing as in the other areas, so that limestone or calcareous ore has to be brought in to smelt it. Ore is exported from Maxeville, the port of Nancy, by way of the Marne-Rhine Canal to Burbach in the Saar Territory. Local smelting takes place near the mines along the Moselle valley, served by rail and water transport, at Maxeville, Frouard and Pompey, and farther south on the Canal de l'Est at Neuves-Maisons; there is an outlying centre in the north, not near any mines, at Pont-i-Mousson. There is a tendency for a greater development in the Nancy region than elsewhere in Lorraine of the manufacture of finished iron and steel products and of engineering, e.g. iron pipes at Pont-i-Mousson, electric locomotives and other electrical equipment at Nancy.

The Metz-Thionville region. North of Pompey mining ceases for 30 km. until the recently developed area of Noveant - Ars-sur-Moselle is reached. Beyond the latter, there is no mining in the immediate neighbourhood of Metz, but the ore field begins again west of Maizieres, 10 km. north of the fortress and continues along the scarp overlooking the Moselle valley to beyond Thionville. The bulk of the mining however is concentrated in the lower valleys of the Orne and Fentsch where adits penetrate the valley sides. The lower valleys of both streams are crowded with iron and steel works, coke ovens, miners' and metal-workers' villages (*cites*), roads and railway sidings. Much of the ore is moved by aerial rope-ways; some travels long distances in tunnels from valley to valley. In the Orne valley a long string of great works stretches from Auboue through Jceuf to Home-court, and again lower down at Moyeuvre and Rombas (Plate 53). In the Fentsch valley there is a similar line from Knutange through Hayange to Florange. There are also several large works in the

Moselle plain, alongside the main railway line—at Maizieres, Hagon-dange, Uckange and Thionville. Many of these works are highly integrated units, producing their own coke and using coke-oven and blast-furnace gases to generate electricity to drive the steel mills and to work the nearby mines.

Fig. 72. Industrial Lorraine. Left: iron mining in relation to navigable waterways. Right: the iron and steel industry in relation to railways

Based on the *Carte Industrielle de la Lorraine* (Paris, 1930).

The most noteworthy differences between these maps and those of the northern industrial region (Fig. 66) are the virtual absence in Lorraine of steel works unaccompanied by blast furnaces, and the presence of numerous blast-furnace works which have no attached steel works. This difference in the economy of the industry in the two areas is a result of their different relations to ore and fuel supplies and to the engineering industries (cf. p. 202).

The Briey region consists of the plateau to the west of the Metz-Thionville area. The self-fluxing ores of this area are mined in the upper basins of the Orne and Fentsch, and in the upper valleys of

the Crusnes basin which drains westward to the Meuse. Mining here is by shafts. Owing partly to difficulties of water supply and partly to those of transport, steel works have not developed on the plateau, and the ore is sent away to the Metz-Thionville district.

The Longwy region lies on the northern edge of the Briey plateau. The international boundary separating France from Belgium and Luxembourg passes along the escarpment on the face of which the ferruginous sandstone outcrops. Mining and metal working are carried on in the upper valleys of the Alzette and the Chiers. The mines are mainly worked by adits, but at Hussigny the ore is quarried in the open. Iron and steel works are crowded in the deep, narrow valleys along the railways. There are half a dozen, some of the most important in France, at the convergence of lines on Longwy-Bas in the Chiers valley, for the ores of this area are so sandy that they do not pay for transport and are smelted on the spot. A second group clusters around Villerupt in the upper Alzette valley.

External relations of Lorraine. Reorientation of the iron, as of the coal industry, of eastern France was greatly simplified by the international nature of the ownership and organization of the Lorraine industries, in which French, Belgian, Luxembourg and German interests were all represented. In spite of transport difficulties, which have always been a serious problem in the working of the ironfield, whether in German or French hands, and in spite also of the decline in the Ruhr-Lorraine interchange of coke and iron after 1918, the export of French ore and pig-iron was already recovering by 1929. In the years 1934-8 the export of pig-iron averaged 6 million tons. During the period 1928-33 Germany imported from France an annual average of 2 million tons of pig-iron, a figure which rose in the years 1934-8 to 6 millions. In the boom years of 1928-30, one-third of the French ore output was exported. From 1933 onwards exports rose owing to the decreased home demand, reaching 19*32 million tons in 1937. Belgium has always been the largest customer for Lorraine ores, taking an average in recent years of 10 million tons. Four-fifths of these imports into Belgium emanated from Belgian-owned mines in Lorraine.

The Northern Region

The iron and steel industry of northern France is based on the fuel supplies of the local coalfield, and is entirely dependent for raw material on ore and metal imported into the area. As a result, pig-iron is not produced in very large quantities—the average for 1932-8 was

less than 0·8 million tons. The steel industry, on the other hand, had grown to considerable dimensions by 1913, and since 1918 has in general maintained a production of between a million and a million and a half tons. Ore and pig-iron are imported from Lorraine, Luxembourg, Sweden and Spain, while some comes coastwise from the Norman ironfield and the smelting works of Caen to the port of Dunkirk. The local metal-using and engineering industries provide abundant scrap for remelting in the open-hearth steel furnaces. In contrast with the Lorraine industry, there are no blast-furnace plants in this area unaccompanied by steelworks, whilst there are a number of steel works which, depending on imported pig-iron and scrap, have no blast furnaces attached. A further contrast lies in the very considerable development in this coalfield region of the manufacture of iron and steel products and of heavy and light engineering industries.

On the coalfield itself, the chief area for iron and steel production centres upon Valenciennes (see Fig. 66). This is the Anzin-Trith-Denain group of works which lies along the canalized Scheldt. Here, in addition to smelting and steel making, both heavy and light engineering is carried on: locomotives, boilers, rails, agricultural and textile machinery. Rail communications are good, coking coal is produced locally, and there are ready markets in Belgium and in the Lille area for semi-finished iron and steel products and machinery. A second, less concentrated industrial area lies between Douai and Lens (see Fig. 73), with steel works at Henin-Lietard and engineering and wire drawing at Douai.

Off the actual coalfield are two other industrial centres. The Sambre valley south-east of Valenciennes is entirely industrialized. Iron and steel production takes place at Hautmont and Louvroil, and here and at Aulnoye, Maubeuge and Jeumont there are numerous heavy and light engineering industries, including locomotive and rolling stock building, boiler making, metal stamping and cutting, the manufacture of iron and steel tubes, nuts and bolts and machine tools. The engineering industries of the Lille area are also considerable; textile and agricultural machinery is made, as well as electric motors and railway rolling stock. Fives and Hellemmes, industrial suburbs on the eastern side of the city, have boiler and locomotive works and metal stamping mills.

Outlying centres of iron and steel production are Isbergues, on the Aire Canal, and Outreau (Boulogne).

Other Areas

The Ardennes. In the department of Ardennes, almost exactly equidistant from Valenciennes, from Longwy, and from Namur, are a number of steel works, metal-using and engineering factories strung

Fig. 73. Industrial Douai

Based on G.S.G.S. 1: 25,000, series 4041, sheet 74 SE.

This map presents a sample of the industrial landscape of the northern coalfield, comprising towns and villages with factories and coal mines in a rural and agricultural setting. The influence of waterways on industrial location is obvious; the map also shows the typical canal basin where barges can be marshalled to await traffic, and the timber basins where pit-props are assembled and distributed. The canals and rivers also supply industrial water and carry off waste. Collieries, often with coke ovens, are usually linked by private railways to the main lines and waterways. The new *cités* (see also Plate 50) are quite distinct in their appearance and layout from the old villages at cross-roads.

out along the meandering river Meuse from its junction with the Chiers above Sedan to the Belgian frontier at Givet, a distance (following the navigable waterway) of just over 100 km. Industry began in the valley on a basis of water power, and it survived by reason of the relatively easy access by water and rail to the Sambre-

Meuse coalfield of Belgium and to supplies of ore, and more especially of metal, from Lorraine. There are steel works at Flize, Mohon (a suburb of Mezieres) and Vireux, and* many foundries, metal-stamping mills and factories making mainly small goods such as hardware, nails, steel strip and wire, at Charleville, Nouzonville, Montherme, Fumay and other smaller places.

The Central region. The iron and steel industries and their derivatives in central France are scattered on and near the small coalfields of the Massif. Generally, these industries depended originally on local ores, no longer worked. Their survival may be attributed to the development of steam power in the small coalfields, to the growth of the great urban centre of Lyons, to the modern development of hydro-electric power, to the cheap labour offered by the isolated highland communities and, not least, to the political necessity of stimulating the growth of vital national industries as far as possible from the north-eastern frontiers. The devastation of the northern and eastern industrial areas during the war of 1914-18 gave a new importance to the industries of the central region. Reconstruction caused an ebb in their war-stimulated activities, but anticipation of a future war prevented a complete return to pre-1914 conditions.

The iron and steel industries of the St Etienne and Le Creusot districts obtain pig-iron from Lorraine, and in addition are supplied by locally smelted iron and by scrap derived from the local engineering industries. The specialized character of the metallurgical work is indicated by the high proportion of the steel output (49% in 1936) classed as 'special', consisting of alloy steels used mainly in the armaments business. The St Etienne region produces good metallurgical coke (cf. table on p. 180). Engineering industries include the manufacture of armaments, cycles and motor-car parts, tools, nuts and bolts and other light metal articles, as well as textile machinery and aeroplane engines. The Gier valley is industrialized almost throughout its length from its junction with the Rhone at Givors to St diamond, and the coalfield industrial belt extends south-westwards across the Rhone-Loire watershed through St Etienne to Firminy. There are several large steel and engineering works which make guns and heavy machinery, while Givors has blast furnaces and locomotive works. In 1936 the departments of Loire and Rhone produced 30,000 tons of pig-iron, 38,000 tons of ordinary steel and 114,000 tons of special steels, including almost the whole French output (about 4,000 tons) of crucible steel.

Farther north, Le Creusot, drawing its iron ore originally from the Jurassic rocks of Berry, no longer makes pig-iron, but depends on coal from Blanzay and Montceau-les-Mines, on coke from St Etienne, on pig-iron mainly from Lorraine, and on scrap from the local engineering works. The great Schneider works contains one of the largest steel-making plants in Europe—it produced almost 150,000 tons in 1936—and extensive armaments and locomotive factories. The town nestles amongst hills, 350 m. above sea level, almost on the Saone-Loire watershed; it is connected by rail and canal with Chalon-sur-Saone and with the upper Loire valley at Digoin.

Isolated centres of metal-using industry within the Central Massif include Thiers, in the Limagne basin, with an old-established cutlery industry, Clermont-Ferrand, of much later development, with light engineering connected with railways and mining. Farther west, in the basin of the upper Cher, are Montluçon and Commentry. These metal-working centres have grown rapidly, favoured by their easy contact with Paris and by access to the Commentry coalfield. The towns are served by the Berry Canal and import pig-iron from Lorraine. There are armament factories and iron-pipe works. Small quantities of pig-iron are made from pyrites and other ores. In 1936, the department of Allier produced 19,000 tons of pig-iron and 27,800 tons of steel.

Out on the plain to the north of the Massif, where the Loire and Allier emerge from the highland, the ores of Berry and the coal of Decize were responsible for the founding of the metallurgical industries of the Nevers district, which now depend on Le Creusot coal and Lorraine iron. There are steel works at Imphy, engineering works including railway rolling stock at Nevers, and other miscellaneous steel-using industries at Fourchambault. Falling within the same metal-working province are Bourges and Vierzon, the former with foundries, ordnance works and more recently aircraft factories, the latter manufacturing agricultural machinery.

Finally, the tally of scattered iron and steel industries in central France is completed with mention of the isolated steel works, with associated engineering industries, at Ales and Decazeville, which are clearly located with reference to fuel supplies.

The Norman Iron Industry. The iron ores of Normandy, Anjou and Maine occur along the edge of the Armorican Massif. For the most part they have been deposited by iron-bearing waters percolating through from overlying ferruginous rocks which are now mostly worn away. In Normandy the ore is mined within the massif, in

Silurian shales; at Falaise, in Maine, it occurs in a Liassic limestone; in Anjou it is worked in the sandstones of the basin of Pouance-Segri. Where erosion of overlying beds of limestone has exposed the ores at the surface, iron carbonates have been converted into iron oxides—haematite; elsewhere the ore is calcareous. In general it is of the granular 'minette' type, and is phosphoric, but is richer than that of Lorraine, having an iron content of 44-54%. The first blast furnaces were erected in 1914; previously to this the ore was worked for export to England and Germany and to supply other French smelting plants. From the Norman fields the ore was railed to Denain and Isbergues in the north; from the southern mines it travelled to the lower Loire furnaces. In 1914 a German firm was about to begin smelting at Mondeville, near Caen, when war broke out and the coke ovens and blast furnaces were taken over by a French company. Pig-iron was first exported from Caen in 1919.

In recent years between 1½ and 2 million tons of ore have been produced in this region, of which about one*third has been used in the local furnaces, and the remainder sent coastwise to the northern coalfield or exported to Britain. In 1936 the output of ore amounted to 1·277 million tons, of which 0·757 million tons was consumed in France (0·555 million tons locally), leaving 0·520 million tons for export. Engineering industries in the area include shipbuilding yards and sea-plane works at Blainville (p. 210), and an aeronautic works at Carpiquet, 7 km. to the west of Caen. The port for the area is at Herouville on the Caen Canal.

The Western region. In western France iron and steel industries are confined to the ports, where they are localized partly by the ease of importing ore, metal and fuel and partly by the requirements of the shipbuilding industry (cf. p. 210). The most important area is the lower Loire. Nantes, with its improved navigation facilities, has developed important metallurgical works, and makes steel castings for naval construction. Basse-Indre, a few miles down the estuary, on the right bank, also has steel works, while Trignac, north of St Nazaire, has a complete plant of coking ovens, smelting and steel works. It makes sheet iron and steel plates for naval construction and guns which go to the yards and arsenals of St Nazaire, Nantes, Brest, and Lorient. There are numerous other steel-using industries in the lower Loire towns, including tinplate manufacture, and Nantes has important locomotive building works.

Iron ore for the smelting works came originally from the Pouance-Segri basin of Brittany-Anjou, and later from Spain and Sweden.

Coal and coke for the iron and steel industries are obtained coastwise from northern France, and steam-coal from south Wales,

An outlying centre of iron and steel manufacture, depending entirely on imported ores and fuel, is Boucau, at the mouth of the Adour river near Bayonne.

Alps and Pyrenees. In these areas development of late years has kept pace with that of hydro-electric power and the use of the electric steel furnace. The production of electric steel in France advanced from 27,000 tons in 1913 to 306,000 tons in 1938, representing in the latter year about 4.2 % of the total output. About one-quarter of this amount was produced in the Alpine and Pyrenean departments. Although the raw material, in the shape of pig-iron and scrap, is bulky, it enters almost wholly into the finished product, with little waste, and the localizing factor is therefore the source of high-voltage electric current which it is inconvenient to transmit over long distances in accidented mountain country. Accordingly, the steel works lie in close proximity to the power stations (Plate 54).

In the Pyrenees, small quantities of haematite ore are mined, mainly in the upper Ariege and Garonne valleys; the reserves are not great however, and output declined from 370,000 tons in 1913 to 27,000 tons in 1936, the bulk of which emanated from the department of Pyrenees Orientales. Small quantities of the ore are fed into the electric steel furnaces, together with much larger quantities of pig-iron and scrap imported into the district. The works are situated at Pamiers and Tarascon, in the department of Ariege.

In the Alps, the output is on a rather larger scale, and in addition to special electric steels there is some production of ferro-alloys which are used in ordinary steel making (ferro-silicon, ferro-manganese, etc.). About ten works are engaged, mostly in the region of the upper Isere and Arc valleys, e.g. Ugine, Venthon, and Montricher, with an important one farther west at Bonpertuis, north-west of Grenoble. The latter town is the only significant locality having any metal-using industries; there are foundries and factories which manufacture electrical apparatus.

SHIPBUILDING

The shipbuilding industry in France has always been on a small scale compared with that of other countries, yet it has a large permanent excess capacity. During the 25 years ending in 1938, and excluding the years 1914-19, it was only in seven years that the output

exceeded 5% of the world total, usually by a small margin only: when it reached 12 % in 1932, the world output was the second lowest since 1909. During this period the maximum French output, in 1921, amounted to 210,000 tons, barely 5 % of the world output. The fact is surprising, for the shipbuilding industry is not generally suited to mass production methods, and would therefore appear appropriate to French industrial and engineering capabilities.

Fig. 74. Distribution of metal-using industries

Based on the *Atlas de France*, Plate 48 (Paris, 1933).

Both ferrous and non-ferrous metals are included, and the industries comprise forges, foundries, rolling and stamping mills, the fabrication of all kinds of metal goods and machinery, constructional, locomotive, electrical and other forms of engineering. The more important individual centres are shown by larger dots.

During the period 1921-6 the output grew as construction was needed to replace war losses, but afterwards declined considerably. French builders cannot compete with foreign builders; in recent years the government adopted a programme of subsidies for ship-

building, but less thoroughly than others. The output remained relatively high when world output fell to a record low level, but declined considerably as world output recovered. Subsidies have not even encouraged an adequate replacement of old tonnage. Tariff reductions were allowed on imported ships since 1936, and in recent years the government set up the Credit Maritime, a system of subsidies to make good in part the difference between French and foreign building prices, whilst early in 1939 an additional grant was offered to encourage the construction of special types of ships, e.g. refrigerator vessels and cargo or passenger liners. Later in 1939 the subsidy was extended to cover orders placed abroad, as many yards were occupied with naval construction. In 1938, for example, Denmark was building five ships on French account, and Great Britain four. In the same year, out of a total world launch of 1,119 ships of 3,033,000 gross tons, 246 of 833,000 tons were ordered for customers outside the countries building them; of these Great Britain launched 56, Holland 53, Germany 47, Sweden 23, and Denmark 19, but France was the only important shipbuilding country in the world not building ships for foreign customers.

Shipbuilding Output, 1930-8

Year	World		France		Percentage of world output
	Number of vessels	Gross tonnage (ooo's)	Number of vessels	Gross tonnage (ooo's)	
1930	1,084	2889'5	18	100'9	3'4
1931	596	1617'1	22	103'4	6'3
1932	307	726'6	23	89'3	12'3
1933	330	489'0	29	34'0	6'9
1934	536	967'4	10	15'9	1'6
1935	649	1302'0	10	42'8	3'3
1936	999	2117'9	17	39'2	1'9
1937	1,101	2690'6	9	26'5	0'9
1938	1,119	3033'6	7	47'3	1'5

The French merchant fleet contains a larger proportion of fairly modern vessels than might be expected from the foregoing account: in 1938 28 % of her ships were less than 10 years old when the average figure for world shipping was 26 %. This was due to the fact that France has a relatively small tramp fleet and assistance to shipbuilding has been effective mainly for the liner fleet. The tramp class includes very few motor ships, and only about 15 % of the fleet is less than 10 years old. Furthermore, governmental encouragement of shipping

has been very effective in the colonial trade; French vessels carry 97 % of the colonial trade but only 40 % of the foreign sea-borne trade.

The advertised figure for total annual construction capacity of the French yards, about 900,000 tons, has little relation to actual output, as the above table demonstrates; a varying amount of this capacity is occupied with naval construction; some yards are not in a state of efficiency; and inevitably every yard is not suitable for building every type of ship. The actual output, in fact, has never exceeded a quarter of the potential capacity. Of the fifteen firms of any size engaged in the industry, four account for two-thirds of the capacity—a greater concentration than occurs in Great Britain.

There are four main centres of ship construction, the Seine and Loire estuaries being the most important. The Loire yards are best known: the largest ships are built at St Nazaire, but the yards at Nantes have a considerable capacity also. The industry on the Seine estuary, while mainly located at the mouth (at Havre and at Gravelle and Harfleur adjoining), has also important yards higher up at Le Trait and at Grand Quevilly near Rouen, as far from the sea as any in Europe. Important secondary centres are on the Gironde just below Bordeaux, and on the Mediterranean, where the sheltered water of the Toulon roadstead offers a favourable position to the principal yards at La Seyne; smaller yards lie on either side of Marseilles at La Ciotat and Port-de-Bouc. A few yards are situated at Dunkirk and at Blainville, near Caen, while there are important naval yards at Lorient and Brest. Since France has no important steel-making centres near the sea, the location of her shipbuilding industries appears to be related mainly to the distribution of suitable launching water, a location, furthermore, best placed in a strategic sense.

The marine engineering industry, however, has a very different distribution, and it is not so closely related to the centres of hull construction as its counterpart in Great Britain; it is clearly less dependent upon natural factors of location or the supply of steel. Two centres are dominant. The Loire estuary possesses a quarter of the total marine engine capacity, and is thus the leading centre of shipbuilding as a whole: the engine works at Nantes are larger than those at St Nazaire. The second important centre is St Denis near Paris, where there are turbine works affiliated to the leading shipyard as well as a large Diesel-engine plant. Marseilles, although it does not build ships, is the third centre in engine-building capacity.

Smaller establishments lie at Cherbourg, Havre, Dunkirk, Bordeaux, and at the naval base of Brest.

LOCOMOTIVE AND ROLLING STOCK BUILDING

The building of railway locomotives and coaching stock is a specialized branch of constructional and mechanical engineering, which began in France about 1840, when the railway was making its debut, and has attained a considerable national and international importance. Contrary to the general practice in Britain, the French railway companies have built but a small proportion of their own locomotives, and although they have large repair works at various localities (see Vol. iv, Ch. iv), new stock has been provided mainly or entirely by engineering firms in different parts of the country. In recent years only the Est works at Epernay and the Nord works at Hellemmes (Lille) and La Chapelle (Paris) have engaged in building. The bulk of the industry is quite naturally attached to the coalfield engineering regions where fuel for foundries and for power is most easily available, and also iron and steel. Since a large proportion of the raw material however—iron, steel, non-ferrous metals, timber, etc.—enters into the finished articles, and since the engines, coaches and wagons are capable of being sent away by rail on their own wheels, the industry is to be found also in odd corners of the country, where it either grew up very early and has remained by sheer momentum (as in Alsace), or has been localized by cheap power (as in the Pyrenees).

The northern coalfield contains some of the most important centres. Lille, Denain and Blanc-Misseron are the chief builders of steam locomotives in this region, whilst other centres, dealing also with coaches and wagons and electric rolling stock, are Jeumont, Raismes (near Valenciennes), Maubeuge and Douai.

On and near the central coalfields, the chief centre is the great Schneider works at Le Creusot, and there are others at St Chamond (near St Etienne) and Givors (near Lyons). In the east, the industry is dominated by the *Societe Alsacienne*, which is one of the largest organizations of its kind in Europe, with works at Graffenstaden (near Strasbourg), Mulhouse and Belfort; there are smaller establishments, dealing mainly in coaching stock and electric vehicles, at Niederbronn in Alsace, and at Luneville and Nancy in Lorraine.

Paris has several works, mainly for coach and wagon building and light railway locomotives, in the northern and north-eastern suburbs—St Ouen, St Denis and Corneuve. Of the outlying centres, the

most important are Nantes, whither the Batignolles locomotive works in Paris were removed in 1921, Bagnères-de-Bigorre, in the Pyrenees, which builds coaching stock, and Clermont-Ferrand, which builds 'Michelin' railcars.

AIRCRAFT MANUFACTURE

This industry is of course of quite recent development; nevertheless, it has undergone a considerable reshuffling within the last decade. In 1931 a first step was taken, for strategic reasons, in the decentralization of the industry. Certain factories were removed to a prescribed zone and their owners compensated. This zone covered the west and west centre of France, between a line drawn through Granville, Le Mans, Orleans, St Etienne, Privas and Nimes, and a line drawn parallel to and 40 km. distant from the coast. Later, twenty-four factories were organized under a form of nationalization; these comprised seven remaining in Paris and seventeen new, enlarged or transferred factories in the west, centre and south. These factories, which were to produce aircraft in series, were organized into six groups; for administrative purposes those of the west, south-west, centre and south-east included plants at Paris as well as the regional plants, while those of the north and Midi consisted only of regional factories. There were, further, fifteen important independent factories, of which ten were in Paris. Thus, of the thirty-nine important establishments, eighteen were situated in Paris and twenty-one in the rest of the country. Many smaller firms remained in the Paris region, together with the majority of component manufacturers (see Fig. 35). In 1938 certain aero-engine works were transferred to such centres as Tarbes, Le Mans and Nevers.

NON-FERROUS METALS

Except for bauxite, the ore of aluminium, France is very poor in non-ferrous metals; neither is there any considerable import of ores or half-smelted metal. There is, in fact, nothing in France corresponding to the great copper and brass industries of Birmingham, for example. For the most part metal production takes place at a small number of factories, situated either on the coalfields or at the ports. Much metal is imported for use in the engineering industries, from Belgium especially, which supplies France with a large proportion of its copper, lead and zinc.

Two factories, one at L'Estaque near Marseilles and the other at Cou^ron near Nantes, smelt 80 % of the lead output, from imported ores. Three factories produce almost all the zinc; two are located on the Haute-Deule Canal near Douai—at Auby and Noyelles—and the third and largest at Viviez, on the Decazeville coalfield. The only nickel works of note is at Havre; it refines metal imported from New Caledonia.

Manganese, so essential to the basic steel industry, is not produced at all in France, and the supplies—about half a million tons a year—are imported from Russia and from British India.

The following table shows the general situation in the production of non-ferrous metals other than aluminium:

Substance	Av. annual consumption ('000 tons)	Percentage home produced	Sources of import
Copper ore	Nil	Nil	
Copper metal	115	1	U.S.A., Belgium, Chile, U.K., Canada
Lead ore (metal content)	12	33]	
Lead metal	100	13	Belgium, Mexico, Tunis
Zinc ore (metal content)	60	2	
Zinc metal	100	60	Belgium, Norway, Indo-China, Spain, Mexico
Tin ore (metal content)	0'5	Nil	
Tin metal	10	5	U.K., Malaya, Belgium, Netherlands, N.E.I.
Nickel ore	Nil	Nil	
Nickel metal	6	70	New Caledonia, Belgium, U.K.

From *Statistique de l'Industrie Mine'rale*, 1936 (Paris, 1938).

Aluminium

Alumina is almost ubiquitous, being the principal constituent of clays, shales, slates and many other rocks, but the commercial ore of aluminium, known as bauxite, is relatively rare. France is one of the few countries of Europe possessing an exportable surplus—the others being Yugoslavia, Hungary and Italy—but reserves are estimated at about 60 million tons, sufficient only for 85 years at the present rate of extraction. The name bauxite is derived from the village of Baux, a few kilometres north-east of Aries, where the earth was first exploited, but the main source to-day, providing over 80 % of the output, is in the valley of the Argens, in the department of Var, within a radius of about 25 km. of Brignoles. Smaller quantities are produced in the departments of Herault (about 11%), Basses-Pyrénées, Lozere and Cantal. The essential content of bauxite is

oxide of alumina, the red colour of the earth being due to staining by iron oxide. The ore is first reduced for the extraction of the alumina. About four-fifths of the bauxite retained in France is thus used—86% in 1936—the remainder being employed in the manufacture of quick-setting cement and of refractory bricks. The production of alumina takes place in the neighbourhood of the bauxite beds, in the department of Bouches-du-Rhone—at Marseilles and Gardanne—where there are convenient deposits of lignite in the Fuveau basin. Considerable quantities of bauxite are exported, mainly to Great Britain (Burntisland) and Northern Ireland (Larne) and to Germany. In 1936 the amount exported was roughly 300,000 tons, about 47 % of the output (Fig. 75).

Fig. 75. Output and export of bauxite, 1913, 1918-38

Although the output has expanded considerably during the last twenty years, the export has not, for concessions to exporters were strictly limited.

The alumina is smelted with the use of cryolite as a catalytic agent, in an electric furnace, because great heat is required for the extraction of the metal. For this process the alumina is sent to the Alpine valleys where hydro-electric power is available. There are about a dozen works, chiefly in the departments of Savoie and Isere (Fig. 79). In Savoie the upper Arc and Isere valleys have works attached to the great power stations, and there are similar establishments in the Greivaudan (middle Isire) valley above Grenoble, in Isere. The total is made up by a few isolated plants in the Alpine region, together with two or three in the Pyrenees, in the upper Ariege basin at Auzat and Sabart

There is little or no employment of the metallic aluminium locally an the Alps. Fortunately, the metal is very light, so that the cost of its transport to the centres of the aircraft and motor industries in which it is chiefly used is not a serious hindrance.

ELECTRICITY

The production of electricity in France was not, until recent years, a matter of planning, but grew up haphazard and as demand increased. The state, however, has encouraged the wide distribution of electricity throughout the countryside in accordance with the policy of checking the drift of population to the towns. Of the communes of France 96 % are now supplied with current.

France produces almost the whole of the electricity consumed within the country, though Switzerland contributes slightly to the needs of the east and north-east. Production is based almost entirely on steam and water power. Of the total installed capacity of 8·5 million kW., 57 million kW. is thermal and 2·8 millions hydraulic; the output of the hydraulic stations, however, is greater than that of the thermal stations (Fig. 76). Thermal generation usually employs coal, but in the north and in Lorraine there is some use of blast-furnace and coke-oven gases for the purpose; a negligible quantity of current is generated by Diesel engines using heavy oil.

Thermal electricity. The thermal generating stations, as may be expected, are situated for the most part on the coalfields—on the main coalfield of the north, on the Moselle coalfield and on all the small fields of the Central Massif (Fig. 78, cf. Fig. 65). Isolated coalfields that contribute are Ronchamp in the south-west Vosges and La Mure in the department of Isere. At Hostens in Gironde and at Fuveau in Bouches-du-Rhone, lignite deposits are used. Blast-furnace gas for generating electricity is used chiefly in Lorraine, and also at the Mondeville works near Caen. At the large sea and river ports electric stations use steam power raised from imported coal.

Within the areas mentioned, the local siting of the power stations is often determined by access to water. For example, Paris, Lyons, Rouen, Strasbourg and Lille have stations situated on important waterways—for a large thermal station not in close proximity to a coal mine must be in a position to obtain coal cheaply by water; and in any case there must be ample water for cooling and a watercourse to carry away condensation water (Plate 57).

The installation of thermal electrical stations on the coalfields and in the regions of metallurgical industry is also due to the increased demand for electric power in the mining and metallurgical industries. Extractive machinery is now all electric, and so, for the most part, is that of the steel works. In fact the bulk of factory machine equipment is now electric. What were formerly waste products—coal slack,

Fig. 76. Output of electric current, 1926-38

Based on successive *Annuaire Statistiques* (Paris).

Although the installed capacity of thermal installations is more than twice that of hydraulic plants, the output of current by the latter is now greater than by the former. The hydraulic plants have for the most part a higher percentage relation of output to capacity than the thermal stations. The increasing cost of coal has led to an increased dependence upon water power; moreover, many of the thermal stations are used simply as supplementary sources of supply at times of low water when the output of the hydraulic stations is at a minimum, or as reserve plants which can be called upon as occasion demands. Thus the Paris area alone has several stations which have been almost or quite disused for some years.

inferior coal, coke-oven gas and blast-furnace gas—are used to generate electricity and utilized in the industry itself. Any surplus current is sold to electricity-distributing enterprises. Of the installed thermal electric power of France, 30 % is to be found in the mining and metallurgical centres. In Paris, however, which has twelve plants with a total installed capacity of 1,723,000 kW., are to be found the most powerful stations in the country (see Figs. 77 and 78). These are all thermal stations, situated on the banks of the Seine.

Fig. 77. Electricity: capacity and output. Above: installed capacity of generating stations by departments, 1936. Below: output of electric current by departments, 1936

Based on *Annuaire Statistique*, 1938, pp. 113-4 (Paris, 1939).

These maps serve further to emphasise the points referred to under Fig. 76.

Fig. 78

Certain thermal installations have their sites decided mainly on grounds of distribution facility, e.g. those of Beautor in Aisne, Mohon in the Ardennes and Vincey in the Vosges, which supply areas otherwise far removed from sources of supply. Others are supplementary to hydraulic installations of unreliable water supply, e.g. Tuilliere on the Dordogne, "Cusset (near Lyons) on the Rhone, and St Tulle on the Durance.

Hydro-electricity. The war of 1914-18 made heavy demands on the coalfields, and the occupation and subsequent devastation of many of the mining areas hastened the scientific development of hydro-electric power. Most of the production takes place south of a line drawn from Strasbourg to Nantes. There are, however, several small installations in Brittany, of which the largest is at Guertedan on the Blavet.

The districts of chief development are as follows:

(i) In the Alps, where the generating stations are very numerous (Fig. 78), but only a few use a great head of water. The tributaries of the upper Isere—Doron, Arc, Romanche and Drac—supply a large proportion of the total number of stations; much of the power in these valleys is used in the chemical and metallurgical industries and by the electrified line of the P.L.M. railway (see Plate 56, and Fig. 79). There are a few stations on the Durance, some on the Rhone just below Lake Geneva, and a small number in the valleys of the Alpes Maritimes. A huge new station at Genissiat, on the Rhone below Bellegarde, destined to become the largest in the country, was in construction in 1939.

(ii) In the Central Massif, a district of later development, there are several large installations, which have necessitated the damming of valleys in the construction of large reservoirs. The largest are those of Brommat, Sarrans and Mareges, the first two on the Truyere, a tributary of the Lot, and the third on the upper Dordogne (Plate 55). Together with Eguzon on the Creuse these stations play

Fig. 78. Location of electric power stations

Based on official sources.

Thermal: the largest thermal stations are all located in Paris; other large plants are to be found mainly on the northern coalfield, the Moselle coalfield, the St Etienne coalfield, on the Lorraine ironfield and at the larger ports. Smaller stations lie on the numerous small coalfields of the Central Massif, and at various scattered towns in other parts of the country; many of the Lorraine plants are also of relatively small capacity, being run by blast-furnace gas mainly for the needs of individual smelting works. Hydro: the largest stations are in the Central Massif; the remainder of the medium sized and smaller stations are clustered in the Alps and Pyrenees, and scattered over the Massif. The flatter northern part of the country has none.

a large part in supplying Paris and the electrified railways of south-western France. Other streams utilized include the upper Tarn, the

Fig. 79. Electric power and industry in the Alpine region

Based on official sources.

upper Vienne, the Sioule, a tributary of the Allier, and the Cere, a tributary of the Dordogne.

Plate 54. Electric steelworks at Ugine (Savoie)

Ugine is in the valley of the Arly, a little north of Albertville; it is the most important electro-metallurgical centre in the Alps. It will be observed that power and heat derived from coal is also employed. Industry here is in a rural setting of vineyards, alpine pastures and forests.

Plate 55. Mareges: dam and power station

One of the largest hydro-electric plants in France, situated on the river Dordogne in the Central Massif. The installed capacity is 132,000 kW., and the average annual output of current 300 million kWh. The river is dammed by a massive barrage, and a head of water amounting to 73 m. is thus created. The station supplies the **Paris area** and also the electrified lines of the P.-O. railway.

Plate 56. Chambon power station

On the Haute-Romanche river in the department of Isere, this is one of the latest additions to Alpine hydro-electric power supplies, opened in 1937-8. It is of relatively small capacity—only 2,070 kW.—but it is fed by a storage reservoir, and so the current generated helps to regulate the variable output of other installations in the same valley.

(iii) In the Pyrenees, the installations are not nearly so numerous as in the Alps, nor of so great capacity as the large ones of the Central Massif, but they mostly employ a great head of water. There are three main groups of stations—in the tributaries of the Adour, e.g. Gave d'Ossau, Gave de Pau, in the upper Garonne and its tributaries the Neste and Pique, and in the upper Ariege and its tributary the Vicdessos. Much of the power is used in the local chemical and metallurgical industries or by the electric railways.

One of the chief difficulties in the utilization of water power in generating electricity is the variability in the volume of water supply. In the Alps, innumerable small waterfalls supply generating stations, but failing a reservoir, the installations all suffer from shortage of water during the frost of winter and during the dry weather of August and September. The stations of the Central Massif also vary to a great extent in output according to season. Here the supply of water is highest in January, March and May, and lowest from July to September. The variability is less marked in the Pyrenean torrents, where, as in the Alps, the peak occurs with the snow-melt in June. Oceanic influence on the rainfall regime gives minor peaks in October and December. In late summer and autumn, however, the supply is very low—only 40 % of the peak.

The Grid. After the war of 1914-18, it was necessary to find markets for the surplus power of the new generating capacity installed, and also means of transmitting the power in a reliable supply to the consumer; so there came about the elaboration of the great distributing organization known as the Grid. This, however, does not exercise such a complete control over power production as the Central Electricity Board in Britain, and there are large numbers of generating stations, especially hydraulic plants, which are of local significance only and are not linked to the Grid, as Figs. 78 and 80 indicate.

The generation and transmission of electric power is in the nature of a service. Electricity is not a commodity that can be stored in large quantity. Its generation, transmission and consumption are almost simultaneous and production depends, therefore, very largely on the hour-to-hour demand of the consumer. But modern electrical technique, which has facilitated the transmission of electric current to great distances, has made possible the organization of a great network of transmission lines, linking thermal and hydraulic generating stations. These stations are grouped in regions, and their management submits to a rigid discipline, so that, in spite of widely

differing capacity and mechanical characteristics, complete synchronization of output can be maintained. This is accomplished by the use of switch and transformer stations erected in the consumer

Fig. 80. The electricity grid

Based on official sources.

High-voltage transmission network and principal power stations supplying current. Lines carrying current at less than 60 kv. are omitted. There are numerous stations, mostly of small capacity, which are unconnected with the Grid system. These mostly serve local industries, e.g. the metallurgical industries of the smaller coalfields and the electro-metallurgical and electro-chemical industries of the Alps and Pyrenees (cf. Figs. 78 and 79, and Plate 56).

districts. Practically all supplies are distributed as alternating current. By means of the Grid, however, supplies to the railways passing through key sub-stations are transformed to railway voltage and rectified to direct current (see Fig. 69 in Vol. iv, Ch. iv). Fig. 80 shows how the various groups of generating stations, most of them

serving local industrial regions, are able to supply distant markets and to supplement each other in maintaining a reliable supply of current. The importance of the Central Massif in supplying Paris and the railways through the great sub-station of Eguzon is clearly seen. Paris also taps, through the sub-station of Grenay (Haute Marne), the Kembs station on the Rhine. By the Henri-Paul sub-station at Chalon-sur-Saone it will eventually be connected with the Rhone station at Cusset near Lyons and with the Alpine supplies. Minor transmission lines connect the Pyrenean supplies with Bordeaux and the lower Loire and with Toulouse and the Central Massif; they also supply the railways. Rouen connects with the north and will eventually link up by a major line with the important sub-station at Saumur on the Loire. This line is not connected with Paris, which is practically independent of the north supplies.

With the development of the Grid, there has been a tendency for the hydro-electric stations to provide an increasing proportion of the national supply. In 1937, which may be regarded as a representative year, the hydro-electric plants were running to full capacity and taking the base load of the Grid, while the thermal plants, in spite of having twice the capacity of the hydraulic installations, were comparatively little used, many of them being in a state of suspended animation. The reason was the shortage of coal and the resulting high cost of thermal electricity. The thermal plants of Lille and Lorraine still carry the base load of their heavy consumption, but many steam plants now, particularly in the Paris area, are redundant.

CHEMICAL AND ALLIED INDUSTRIES

Two factors have greatly influenced the development of French chemical industries in the last quarter of a century. One is the fundamental reconstruction of industry in the coalfields since 1918, and the other is the setting up of hydro-electricity services in southern France as a result of the scarcity and cost of home-produced coal. To these two factors may be added the stimulus afforded by the political movement towards self-sufficiency which has characterized European policy for some time past.

The chemical industries may be divided into those based on the coalfields and coal-importing ports and those based on hydro-electricity.

Coal Distillation Products

The chemical industry has greatly benefited by the discovery of the uses which can be made of the waste products of the coke ovens, retorts and blast furnaces—gas, coal-tar, ammonia, basic slag, etc. To-day, the profits from the former 'waste' products often greatly surpass those from the sale of the coke. For example, the output of the Bethune mines yields something like 15,000 tons of coal tar, 53,000 tons of sulphate of ammonia, and 3,000 tons of benzine products a year; while that of the Lievin mines produces 7,500 tons of coal tar, 951,000 litres of benzine products for motor fuel, and 87,000 litres of naphtha solvent. The synthetic petrol installations of Bethune and Lievin were able to produce, by 1937, 6,000 tons of petrol a month. The Bethune and Courrieres mining companies also manufacture methyl and ethyl alcohols. The Lens company makes synthetic formol used in the manufacture of resins. In Lorraine the La Houve mine produces coal tar, sulphate of ammonia and synthetic ammonia among other products.

Output of Coke and Distillation Products', 1936
(in thousand tons)

	Coke	Tar	Sulphate of ammonia	Benzol	Gas (mill. cu.m.)
From coke ovens:					
Metallurgical coke	5,038				
Other qualities	2,063	268	88	76	2,757
From gas works	1,859	206	16	12	1,559
Total	8,960	474	104	88	4,316

Coke and Gas (see Fig. 67). Of the 7'1 million tons of coke produced by about 3,600 coke ovens, 3'9 million tons came from pithead cokeries (mainly in Nord and Pas-de-Calais) and 2'6 million tons from cokeries attached to smelting works (mainly in Lorraine). The coke ovens consumed 9'2 million tons of coal, 60% of it French, 21 % German, 12 % Belgian, and 4% British. Of the gas produced almost exactly one half was employed for heating furnaces; only 6 % was used for the extraction of by-products, and the remainder passed to industrial and domestic consumers.

The production of gas-works coke as a by-product of the distillation of coal in retorts is naturally far more widespread, for there are gas works in every department of the country. The great gas works of

the Paris area however (department of Seine) are responsible for about 40% of the entire output. The gas industry in 1936 consumed about 3'9 million tons of coal, 64% of it being of French origin, 22 % British, and 13 % German. The British coal was used especially in Paris, at the west coast ports of the lower Seine, Loire and Gironde, and on the Mediterranean coast.

Coal Tar and Coal-Tar Products. The production of coal tar has remained at a level of about half a million tons a year for some years. One ton of coal yields about 1 cwt. (50 kg.) of tar. Sixty per cent of the output comes from the northern coalfield, Lorraine and Paris. In addition to the French output, some 230,000 tons of tar were imported, mainly from Britain, making a total consumption of about 700,000 tons. Of this amount about 600,000 tons were submitted to further distillation; 390,000 tons were partially distilled only, to produce road-surfacing material. The pitch derived from the distillation is used in the manufacture of patent fuels {*briquettes* and *boulets*), for which there are about 120 factories, located for the most part on the coalfields or at the ports where coal and tar are imported.

Patent Fuel Production, 1936 (in thousand tons)

Region	Department (locality)	Output
Northern coalfield	Nord	2,777
	Pas-de-Calais	913
Central coalfields	Gard (Ales)	1,140
	Loire (St Etienne)	424
	Saone-et-Loire (Blanzy)	323
	Tarn (Albi)	104

The most important of the products of further distillation is benzol, from which, by successive distilling, are derived naphtha, creosote products, lubricating oils and benzine for motor spirit; another is naphthaline, from which in turn are derived aniline for dyeing processes and also explosives, tear gas and perfume products. The output of benzol from coke ovens and gas works in 1936 was 88,000 tons, but this did not suffice for home consumption which in the same year amounted to 105,000 tons and in 1937 had risen to 121,000 tons.

Synthetic petrol to the extent of about 1,000 tons a month can be produced by the installations at Bethune, Lievin and Paris.

The quality and range of *dyestuffs* have increased enormously of

late years. They are manufactured on the coalfields conveniently adjacent to the supply of coal tar and sulphuric acid, and also at the ports, both maritime and fluvial, e.g. Paris, Creil, Lyons, Troyes and Oissel near Rouen. Proximity to the textile industry is obviously a locating factor.

Chemical fertilizers. Of the coalfield fertilizer products, sulphate of ammonia is one of the most important; the average annual production in the years 1934-7 was 302,000 tons. Basic slag, residual from the smelting of phosphoric ores, comes also from the northern coalfield and from Lorraine. Over a million tons were produced in 1936. One of the artificial manures, superphosphate, is manufactured chiefly at the ports, e.g. Rouen, Nantes, Tonnay-Charente, La Pallice and Bordeaux, with the aid of sulphuric acid and imported phosphates from the French North African possessions. North Africa and France together produce over half the world's supply of phosphate rock, and the French output of superphosphate is over a million tons a year. For sulphuric acid manufacture the chief raw material is iron pyrites. There is a deposit at Sain-Bel, 20 km. west of Lyons, in the schists of the Central Massif, but half a million tons a year are imported, mainly from Spain and Portugal. Copper pyrites may also be treated, and a factory at Port-de-Bouc produces, as a by-product, copper sulphate for vine spraying.

Potash. France is fortunate, so long as she possesses Alsace, in having one of the two richest deposits of potash in Europe. The salt lies beneath the forest of Nonnenbruch, just north of Mulhouse (Plate 58). About a score of mines are connected with the Colmar-Mulhouse railway. The deposits contain 12-22% pure potash. They were discovered about 1900, but were only fully exploited after the recovery of Alsace by France. The reserves are estimated to last 500 years at the present rate of extraction. In 1926, competition with the German Stassfurt salts became so acute that it was necessary to negotiate an agreement, by which 30 % of the French and 70 % of the German product might be marketed up to a total of 800,000 tons of pure potash output, beyond which equal amounts might be sold. This agreement was to some extent undermined by intensive development of resources in Spain, the U.S.S.R., and the United States. From a peak output of 3 million tons in 1929 the Alsace production fell to 1'9 millions in 1932 but had recovered to 3'2 millions in 1938. The oldest and largest company is that of the ex-German *Mines Domaniales de Potasse d'Alsace* near Mulhouse. It was purchased by the state in 1924.

Plate 57. The power station at Comines

Plate 58. Potash mine in Alsace

The Amelie II Mine, north of Mulhouse. The potash is obtained from rocks of Oligocene (Lower Tertiary) age, at depths of from 200 to 700 m. The discovery of the mineral has brought industry and people into the midst of the ancient forest of Nonnenbruch.

Plate 59. Salin des Pesquiers (Var)

Salt-pans on the edge of the Etang des Pesquiers, a few km. east of Toulon.

Other French sources of potash are at Boudigot in the Landes; there is also potash, unworked at present, in the Montagne Noire in Languedoc. Of the potash mined for export, nine-tenths goes by water from Strasbourg to Antwerp, as it is too expensive to rail the salt to Dunkirk. In recent years between 20 and 25 % of the output has been exported, and the rest consumed in France. The chief customers for the exported salt are Belgium-Luxembourg, Holland, the United States and Great Britain.

Common Salt occurs as rock salt in the Lias clays of Lorraine where it is mined in the valley of the Sanon, tributary of the Meurthe. Most of the salt is, however, extracted by solution and brine pumping. There are brine pits and refineries at Varangeville, at RosiÈres-aux-Salins and also at Dombasle, where the great Solvay soda works are situated. Salt is exported from this district by rail and canal to Paris, Rouen, Lille and Maubeuge to supply glass and pottery works, textile, soap and paper factories, as well as for domestic use.

Salt also occurs farther north in the department of Moselle, where the Seille river basin is dotted with depressions filled with shallow lakes, the result of subsidence caused by the pumping of brine from the underlying salt deposits. CMteau-Salins and Dieuze are centres of salt refining, and Dieuze has chemical works dependent on the local brine. Apart from these two main sources of common salt, there are deposits at Lons-le-Saunier and Poligny on the edge of the Jura in the Franche-Comte area.

In the Mediterranean region, salt is obtained by evaporating water from the lagoons along the coast in salt-pans. Chemical industries at Marseilles are supplied from this source (Plate 59).

Electro-chemical products (Figs. 79, 81)

The development of electro-chemical industries has accompanied the development of hydro-electric power supplies. The making of calcium carbide and its fertilizer derivative calcium cyanamide requires the very high temperatures of the electric furnace. Calcium

cyanamide is used for making synthetic nitrogen from the air for explosives and for manures. Numerous chemical works are attached to the hydro-electric stations in the Alps and Pyrenees. In the Alps they are located chiefly in the Doron, Arc and Romanche valleys; the largest installation is at l'Argentiere near the head of the Durance. In the Pyrenees the largest plant is at Auzat in the Vicdessos valley.

Based on *Annuaire Statistique*, 1938, pp. 113-4 (Paris, 1939).

Miscellaneous Industries

Oil refining. France's production of crude oil is almost negligible. The oil wells of Pechelbronn in Alsace, stretching in a line from Morsbronn to Cleebourg, provide less than 1% of the French consumption of mineral oil, which in 1936 amounted to 6 million tons. The refining of imported oil, however, has made great strides of late years. The first step was the acquisition of control over supplies of crude oil, through French participation in the working of the Iraq

oilfield. A national company, *Compagnie Franfaise des Petroles*, was formed in 1924 to carry out this work. Later came the establishment of a refining industry in France. A second national company was formed in 1929, the *Compagnie Franfaise de Raffinage*, 55% of the capital being subscribed by the *CF.P.*, 35% by a group of French

Based on official sources.

The refineries shown are complete plants, equipped for all refining processes. Smaller plants, with a limited range of refined products, are omitted. A few major towns are indicated by initials.

marketing concerns, and 10% by the government. This company built two refineries, one at Gonfreville-Orcher near Havre, which commenced production in 1933, and the 'Raffinerie de Provence' at Martigues, which began in 1935. Several smaller refining companies were also formed. Furthermore, the imposition in 1928 of a customs duty on imports of gasoline and other refined products had the effect of encouraging foreign interests to undertake refining in France, and

refining companies were formed by the leading international concerns with French capital participating to some extent. Eventually, fifteen complete oil refineries were established, all but two of which lie on or near the coast. These had, in 1939, a total annual refining capacity of 9 million tons, distributed as follows: *Compagnie Francaise de Raffinage*, with two refineries, 27 million tons; other French companies, with five refineries, 1'3 million tons; *Royal-Dutch-Shelly* with two refineries, 1.5 million tons; *Anglo-Iranian*, with two refineries, 0.8 million tons; other companies, mainly American, with four refineries, 27 million tons.

The geographical distribution of the refineries is shown on Fig. 82. Of the thirteen large coastal and near-coastal refineries, four, including the two largest, are located on the lower Seine, three on the shores of the Etang de Berre, four on the middle west coast near Bordeaux and St Nazaire, one near Sete and one at Dunkirk. Of the inland plants, one is at Courchelettes, near Douai (see Fig. 73), and one on the oilfield at Pechelbronn.

A few other refineries, of a more or less specialized nature, deserve mention. That at La Mailleraye, on the Seine below Rouen, is the oldest in France; it specializes in white oils, from which lubricants are derived. At Autun, on the Autun-Epinac coalfield, there is a small refinery which treats locally produced shale. In recent years several experimental plants have been established to produce oil from coal by the hydrogenation process; their total annual capacity was 40,000 tons of aviation gasoline. The chief is at Mazingarbe, near Bethune; others exist at Lievin and at Haines, near Calais. The production of substitute fuels has also expanded in recent years, and the alcohol industry, mentioned below (p. 233), has yielded annually some 200,000 tons of automotive fuel.

Vegetable oil refining. Another industry that has associated itself with the ports and has achieved considerable importance of late years is the crushing of oil seeds of various descriptions, the extraction and refining of the oil, and its treatment, together with animal fats, in the manufacture of soap, candles, margarine, etc. Marseilles is one of the greatest importers of tallow and oil seeds and has great and old-established factories; but Paris, Lyons and Nantes now also have large installations. The modern processes of hydrogenation, etc. have made possible the utilization of a great variety of vegetable and animal oils. Marseilles employed originally local and then African olive and palm oil in the production of soap and candles. To-day many kinds of eastern oil seeds are used as well—cotton seed, linseed,

palm kernels, copra, soya beans and many others. The northern ports use larger proportions of whale oil, linseed and cotton-seed oils. Alfortville and Maisons-Alfort in the Paris area have large soap works. Nantes makes oil for sardine preserves. The manufacture of oil cake for cattle food is a subsidiary industry in all the large ports.

Plastics. The plastics section of the chemical industry has for long been a special activity in France, developed by highly skilled craftsmen in the Jura district. The making of pipes and combs, etc. from local boxwood was greatly developed when, with the exhaustion of this raw material, plastic materials, such as vulcanite, celluloid and casein, were introduced. All kinds of articles are manufactured—domestic utensils, toys, dress ornaments, surgical appliances, glass substitutes, etc. In the highlands the industries are largely carried on in cottage and small factory units.

Paper making. This industry requires plenty of running water, preferably with a high degree of hardness, and the older mills are situated in valleys where swift streams could provide power and carry off the waste—the streams of the chalk region of Artois, for example, or those of Caux in Normandy. Some of the Alpine and Pyrenean streams provide power for paper mills, e.g. in Gresivaudan and the Salat valley. The chief raw material is wood pulp, easy to transport in the dried form in which it is imported from Sweden. Local wood pulping is associated with paper mills, as in the Vosges, near Epinal. Reeds from the Camargue—the Rhone delta—are used in the manufacture of cellulose.

Cement. The abundant distribution of limestone of various types has been a great asset in the major industry of cement making. The industry is fairly widespread, though certain concentrations are naturally observable in the main regions of limestone and chalk outcrop.

Six broad regions are distinguishable, (i) The most important is the northern chalk region extending from the channel coast in the region of Boulogne through Artois to the St Quentin-Laon district. Here the chalk marl is used in the manufacture of Portland cement; about one-fifth of the entire French output comes from this region, (ii) The lower Seine and Oise valleys between Paris and Mantes have several large works using chalk and Tertiary clays, also for Portland cement (Plate 60). (iii) The same product is derived from the Jurassic limestones in Lorraine, where too the slag from the iron works is used as a raw material, (iv) The Jurassic limestones on the south-eastern flanks of the Paris basin are also used in the departments of Yonne

and Cher; much of the output of the works in the Loire valley in Cher is hydraulic cement, (v) The Aquitaine basin, with abundant limestone of various types and ages, has several producing regions, concentrated in the neighbourhood of Bordeaux and Angoulême, and more scattered in the departments of Tarn, Lot-et-Garonne and Dordogne, the last-named specializing in hydraulic cement, (vi) In the south-east the Jurassic and Cretaceous limestones yield cement in four main areas—in the Grenoble-Chambery-Amberieu district of Isère and Ain, in the south-eastern corner of the country in Alpes-Maritimes, in the Marseilles region in Bouches-du-Rhône, and in the Rhône valley in the limestone area of lower Vivarais, where Le Teil (in Ardèche) makes hydraulic cement.

Cement Industry, 1936 (in thousand tons; only departments using more than 100,000 tons of limestone)

Region	Department	Limestone and chalk quarried	Cement output
The North	Pas-de-Calais	1,263	824
	Nord	252	213
	Aisne	256	217
Lower Seine	Seine-et-Oise	966	800

	Alpes-Maritimes	235	189
	Ardèche	368	317
	Bouches-du-Rhône	465	296
All other departments		1,209	1,131
Total		7,584	6,018

From *Statistique de l'Industrie Minière*, 1936 (Paris, 1938).

In addition to the 7·6 million tons of limestone and chalk employed in the cement industry, 0·7 million tons of clay and 0·5 million tons of slag were used. Small quantities of bauxite were employed in the manufacture of special quick-setting cement. Finally, nearly 11 million tons of sand and gravel were quarried in 1936 for making mortar and concrete.

Gypsum for the manufacture of plaster of Paris is dug mainly in the Marne valley east of the capital; the three departments of Seine, Seine-et-Oise and Seine-et-Marne in 1936 produced 860,000 tons out of a total French output of 1,344,000 tons.

Rubber. The resins form the basis of another group of chemical products. Of these rubber comes first in importance. The raw product is not costly to import or transport and the location of the rubber industry has no geographical significance, except that it appears to avoid the frontiers, being located chiefly in the upper Loire district at Clermont-Ferrand and Montluçon. These two towns are the seats respectively of the Michelin and Dunlop motor-tyre works (see Plate 70). St Ouen in north Paris and the Ivry-Vitry district of south Paris also have rubber works. To-day, reclaimed rubber is increasingly used.

Alcohol. The distillation of alcohol from potatoes and beet root is an old industry. Since 1918 the innumerable small refineries have been to a large extent replaced by larger establishments. They are situated in the north, where the cultivation of beet is carried on, and are as ubiquitous as the sugar refineries of Picardy, Artois and Santerre. Paris also has great distilleries.

TEXTILE MANUFACTURES

The French textile industry is very widely disseminated (Fig. 83). True, there is major concentration on and in the neighbourhood of the northern coalfield, and the formerly scattered Norman industry is now concentrated about Rouen, but the old-established industries of Reims and Troyes are still important, and those of the upland valleys of the Vosges, Jura and Alps have retained their position to a great extent. Mulhouse and Lyons, however, exert a strong centralizing force.

There are four major textile regions (Fig. 84): (1) in the north, focused on Lille, where the cotton industry takes the first place, but where linen, woollen, rayon and mixed fabrics are also important; (2) in and around Rouen, where cotton spinning is the main activity, but where wool and linen are still important; (3) Alsace, where the cotton- and calico-printing industry is focused in Mulhouse and cotton weaving spreads across the Vosges; (4) the widespread Lyons region, where silk and rayon are the main interests.

The French textile industry has retained to a much greater extent than that of iron and steel the characteristic feature of small family

concerns, even in the spinning section, but to more marked extent in the weaving. There is little sign of vertical integration, another notable contrast with the metallurgical and coal industries. Only about one-half of the cotton industry has combined spinning and weaving units. There is great local specialization, even in the major

Fig. 83. Distribution of textile industries

Based on the *Atlas de France*, Plate 49 (Paris, 1933)-

This map indicates the widespread character of the textile industries in France, while also suggesting certain major concentrations (cf. Fig. 84). The more important individual centres are shown by larger dots.

divisions of the industry. The northern area, for example, is more engaged in spinning yarns than in weaving, whereas in the western Vosges the two activities are equally divided. Possibly the softer waters of the Vosges may be a factor here. Calico-printing is a speciality of the Alsace textile area. In the Lyons silk area, too, there is local specialization, the ribbon making of St Etienne being an example.

The Woollen Industry

The manufacture of wool and flax early concentrated in the Flanders plain. Wool was imported from England and cloth-making flourished. With the development of steam power, wool combing became a special Occupation in the neighbourhood of the Belgian frontier, centring at Roubaix and Tourcoing. London re-exported

Fig. 84. Distribution of textile operatives by departments, 1936

Based on *Recensement genéral, 1936, Tome I* (Paris, 1938)

large quantities of wool to this district before 1914, and the combed wool found good markets in continental Europe. After 1918 the reconstructed industry made great strides and began to specialize in light cloths, particularly for women's wear. Soon this industry was as well equipped as any in the world. Alsace also has a considerable share in it, chiefly at Colmar and Mulhouse, and the old woollen town of Elbeuf, near Rouen, revived its industry as a result of the 1914 invasion of the north. Some 90 % of the raw wool is imported.

France now imports directly from Australia, short circuiting the London market. She also imports considerable quantities from South Africa and small amounts from Algeria.

At the last census 167,500 persons were employed in the woollen industry as a whole (cf. table on p. 173). Over half the mills employed less than twenty-one hands and only eleven firms employed over 1,000. In the weaving, as many as 14·1% are family establishments, and 35·5 % of the mills employ only one to ten hands. Only 2·3 % have between 500 and 1,000 workers and only 1·7% over 1,000.

The bulk of the worsted is produced in the Roubaix-Croix-Tourcoing district, which makes 80 % of the worsted and wool-mixed hosiery and produces most of the yarns and finished goods, particularly dress goods. From French Flanders the industry spreads over the chalk divide into Picardy and Cambresis, where dress materials are also made. A large number of small towns specialize in some type of woollen product: Sedan retains an ancient heavy cloth industry, Reims and the neighbouring villages make flannels, Orleans is the chief blanket-making centre, Chateauroux makes cloth for military uniforms; Mazamet, in the south-west Central Massif, imports sheep fells from Argentina and specializes in 'plucked wool', which finds a market in England. The skins are sent to Craulhet for the leather industry. In the valleys of Aude and Tarn, rabbit fur is used in making felt.

The post-war prosperity in the woollen industry came to an end in 1930, when the depression was further aggravated by the closing of the German frontier to French combed wool.

Linen

The linen industry still holds an important place in French textile activities. It kept its hold long in the north, largely because of particularly favourable conditions for flax growing in Flanders and for flax retting in the waters of the Lys valley (Plate 61). There has been a steady decline, however, in the growing and preparation of flax, and for many years most of the fibre was imported from Russia. The number of persons employed in the retting and scutching of flax has dropped to about a thousand, and most of the works even of the Lys valley now lie on the Belgian side of the frontier. The area under flax was lowest in 1932, in spite of state assistance to the growers. Reconstruction after 1918 gave a temporary prosperity. World-wide troubles coincided with a rise in the price of raw material owing to the decrease in flax acreage in Russia; at the same time the com-

Plate 60. Cement works at Gargenville, near Mantes

Between Paris and Mantes the river Seine has cut through the Tertiary rocks which form so much of the surface of the Paris Basin to the chalk beneath. The chalk is quarried on a large scale at several works such as this. Coal (British or French) is obtained, and the lime and cement are largely sent away by river.

Plate 61. Flax-retting in the Lys

The operation of removing the fibres from the vegetable matter which surrounds them is performed by steeping the flax stalks in water. The harvested flax is placed in large open-sided wooden cases, which are weighted down with stones. On the bank small stooks of flax are seen drying, after harvesting and before retting.

Plate 62. A section of industrial Roubaix

In the centre, the Roubaix Canal, with quays and a lock; on the left, a patent fuel factory, gas works and a coal depots each with its own quay; on the right, numerous textile mills.

petition of cotton, jute and wool and more particularly of rayon became serious. The slump in hand embroidery caused by the introduction of the sewing machine and the unhealthy conditions of the industry were contributing causes. Flax preparation and spinning requires damp, warm conditions, and flax dust is harmful. Much of the labour employed in France comes from Belgium. There are about 600,000 flax spindles, 22,000 power looms, and it is estimated that about 18,000 hand looms are installed in cottages. Altogether 22,000 hands are employed in the spinning section. Climatic conditions confine the spinning of flax to the north of the country. Lille has four-fifths of the spindles, and the rest are distributed in French Flanders, the Somme basin, Normandy and Brittany. Cambrai, Amiens, Abbeville, Barentin (near Rouen), Rennes, Angers, Cholet and Lige are organizing centres. Weaving, employing about 56,000 people, is also carried on chiefly in the north. Some weaving is done in the spinning towns mentioned, and Armentieres, Hallines, Bailleul, Hallencourt and Valenciennes in the north, Lisieux in Normandy and Gerardmer in the Vosges specialize in weaving (Plate 64). Goods manufactured vary from the coarsest sail cloth to the finest cambrics.

Cotton

Rouen. The cotton industry took root first in Rouen and the surrounding district and proved at once a serious rival to that of linen, which had developed along the stream valleys of the plateau of Caux, overlooking the Seine. Its dependence upon imported raw material encouraged development along the Seine waterside, and a continuous line of textile factories follows the loops of the river for a score of miles above Rouen and spreads up the valleys that converge on the town (cf. vol. iv, Fig. 14, and see Plate 63). Raw cotton is railed from Havre, which supplies practically the whole of France. Rouen is in the main a spinning district, but produces also heavy cottons, e.g. twills and cretonnes.

The North. Naturally the industry quickly established itself also in Flanders in contact with the coalfields and with an available supply of textile labour. Proximity to the coast was also a geographical asset, encouraging the manufacture of yarns for export. Lille itself specializes in the higher counts for quality piece goods such as muslins and voiles, while Roubaix and Tourcoing with Armentieres use the lower counts. The hosiery and knit-wear side of the industry is centred in Roubaix (Plates 62 and 63).

Alsace. The cotton industries of the eastern industrial area are to be found in the valleys of the Vosges, in Alsace, Lorraine and the Belfort district. Calico- and muslin-printing works were set up in Alsace in the eighteenth century, and this branch has been maintained to the present day. Important technical and art schools specialize in designs for fabric-printing. The spinning of cotton came later, establishing itself as a cottage industry in the Vosges valleys and all the valleys of upper Alsace. It was not long before the introduction of steam power caused a concentration of labour on the plains in and around Mulhouse and Colmar. The valleys, however, continued to work for these controlling centres. One result of the Franco-Prussian war and the annexation of Alsace was the exodus of many Alsatian cotton masters to the western flanks of the Vosges and to the Belfort district. It was the nodal town of Epinal that organized this immigrant addition to the Lorraine textile industry. Within 30 years, 1870-1900, the population of the town rose from 8,000 to 28,000. Cotton spinning developed rapidly to feed the already established looms and calico-printing established itself at Epinal. Good communications were an important factor in this development, trans-Vosgian roads and railways and the Canal de l'Est playing their part. The St Die region is the seat of an early Alsatian colony of 1797 which introduced the cotton industry, affiliated to parent institutions in Alsace. This facilitated the later migration after 1872.

The reacquisition of Alsace after 1918 was hardly an asset for the over-producing mills of Lorraine, but by 1920 adjustment had been accomplished.

In the St Die district all branches of the cotton industry are carried on, down to the making up of clothing, but within the area certain centres specialize: e.g. Provencheres is a spinning and weaving centre; St Die has hosiery and dye works; bleaching is carried on in the Raon district. On the whole, Alsace produces the higher quality yet popular piece goods—zephyrs, twills, printed muslins and calicoes and fancy goods generally—while the Vosges valleys of Lorraine manufacture coarser grades of the same types. The latter region, with St Die in particular, makes a great variety of textiles in which cotton and silk are combined. One speciality, deriving from the former metallurgical industry, is that of metal thread weaving. It is interesting to note that, though the bulk of the Vosges inhabitants are Catholic, all the cotton workers are Protestant.

Troyes. Of the textile industry of Troyes, also established by colonies of Protestants, the revocation of the Edict of Nantes left

only a remnant—the knitting industry, which later developed into the hosiery and knit-wear manufacture. Troyes is the centre of a group of small towns in the department of Aube—Romilly-sur-Seine, Aix-en-Authe, Marigny and Mery—which have knitting factories, and there is a considerable development of cottage industry using small hosiery machines.

Central Massif. A group of small centres, affiliated to St Etienne and Lyons, make cotton goods as well as silk and rayon. Such are Roanne and Thizy, which make fancy goods for dresses, shirtings and woven coloured goods, and Tarare, whose many small workshops turn out muslins, tarlatans and specialize in surgical dressings and bandages. Cholet, near Nantes, makes cotton handkerchiefs.

Employment, etc. The cotton industry employed about 192,000 persons in 1938. As in other textile industries of France, the undertakings are generally small. In 1931 the average number of persons employed per spinning mill was only 216, and per weaving unit 119. Only 10 units employed over 1,000 hands and 105 weavers employed no wage earners.

This results from the highly individualized nature of the industry, in which, according to tradition, novelty spells success. There is great variation in the nature of goods produced within each area and wages vary greatly. Little or no central organization has developed, though there is a cotton-conditioning office at Havre, the chief port of raw-cotton import, with a branch at Dunkirk.

The industry as a whole has not encouraged the installation of modern machinery. In 1938 only 19·5 % of the looms were automatic. The small manufacturer has little capital to invest, and apart from the high cost, automatic looms are held to be unsuitable for the great variety and high specialization of the French product, which is very sensitive to changes in fashion. Also there are labour difficulties in the installation of machinery, which reduces the number of operatives required.

A large proportion of the loom machinery is manufactured in Alsace. Spinning machinery still comes from the United Kingdom. Switzerland and Germany provide the hosiery machinery and Germany the calico-printing plant.

Silk

The silk industry was started in the Rhone valley by Italian immigrants in the fifteenth century. They introduced the rearing of silkworms into Provence and Languedoc and this spread up the

Rhone valley to the plains around Lyons, accompanied by the cultivation of the mulberry tree. Sericulture was at that time a boon to the poor farmers of the edge of the plain, giving occupation to the women and children and thus making a welcome addition to the cottager's income. Silk reeling and spinning had not the same climatic restrictions as silkworm rearing, and spread from the lower to the middle Rhone valley and into the valleys and intermontane plains of Savoy and Auvergne. Radiating from its control centre at Lyons, where at first the hand-loom weavers lived and worked in the district of La Croix Rousse, in the angle between Saone and Rhone (see Plate 74), it became established in the plain between Vienne and St Rambert, in the upper Rhone valley at Bellegarde and Nantua, and in the southern valleys of the Jura—Ain and Alberine. It extended also along the Gier valley to the Loire basin at St Etienne and Roanne, where silk ribbons became a specialized product. To-day, the weaving mills are chiefly in the departments of Rhone, Isere and Ain. There are about 350 silk-weaving units in the department of Isere alone.

Although the circumstance of its initiation was historical, the persistence and development of the industry were due to climatic and social conditions encouraging sericulture, to the presence of cheap skilled labour, drawn from and utilized in the highlands, and to the swift streams of the uplands. At a later stage it depended for power on the scattered coalfields of the massif and, in more recent years, on the hydro-electricity of Alps, Jura and the Auvergne.

Sericulture, which in the middle of the last century produced annually about 12,000 tons of cocoons, has steadily declined. By 1914 the output was halved, and in spite of state encouragement, which kept the average up to 3,500 tons between 1924 and 1927, had dropped to 943 tons by 1933. By 1938 it had declined still further to 597 tons. Reasons may be found in the falling off in the rural population, in the onerous nature of the work, aggravated by the spread of silkworm disease. The competition of the products of overcrowded rural districts in Italy soon made itself felt, followed by that of Syrian and Chinese cocoons. Finally, Japan captured the French market, ousting in the past few years the Italian product. Japan is to-day the main source of floss silk. The French raw-silk production during 1935-7 was only 2 % of the total amount consumed,

Lyons. Four-fifths of French silk goods are manufactured in the Lyons-St Etienne industrial area. Because of the immense variety of silk products and the susceptibility of the industry to changing

Plate 63. Tourcoing

Tourcoing, with its neighbour Roubaix (see Plate 62), is one of the most important textile centres of France. The photograph shows the outskirts of the town. In the foreground is a typical weaving mill, with serrated roof of glass; all around are workers' dwellings, allotments, and open spaces. In the distance is the cultivated plain of Flanders and a large village which has almost been absorbed by the spread of the town.

Plate 64. Elbeuf, on the lower Seine

A view looking south-eastwards, upstream, across this textile town which is situated on the concave bank of a great sweeping river meander at a point where a small tributary comes down from the chalk plateau. The many mill chimneys are a prominent feature.

Plate 65. Gerardmer, in the Vosges

The chief centre in eastern France of the linen industry, which is conducted in small mills such as the one in the foreground, and in domestic establishments. Much of the bleaching section of the industry is located in a neighbouring valley, on meadows by the side of lake Longemer.

fashions, the tendency to dispersal has persisted (in spite of the installation of some large mills), being greatly encouraged of recent years by the supply of electricity to outlying valleys. Lyons organizes this scattered and heterogeneous production in close collaboration with the fashion masters of Paris. The cottage and small-scale units which make so much of the elaborate fancy goods are very flexible in their organization, and if work fails for a season, there are the rural occupations of pasture and forest for the peasant to fall back on. More than half those employed work in mills with less than 500 hands, and over 1,000 establishments employ fewer than 100 workers. There are about 3,800 isolated works in all.

Vosges. Some silk is manufactured in the Vosges valleys. Mulhouse employs 2,000 hands in the silk and rayon industries. Soultz has an important 'schappe' silk industry for the spinning of which silk waste from the Lyons industry is used. The thread is sent to Basle to be twisted. Silk hosiery is made at Barr.

Troyes uses locally manufactured silk and spun silk in the hosiery industry.

Rayon

In 1938, France produced 28,000 tons of rayon, and ranked as sixth among the world's producers. Within recent years, the rayon industry in France has shown signs of becoming a close monopoly; over two-thirds of the production is controlled by the *Comptoir des textiles artificiels (C.T.A.)*. The viscose and acetate methods have now completely superseded the older preparations with nitrate and copper, which were both unsatisfactory and expensive. The viscose method was commercially exploited as far back as 1900, but owing to the mediocre quality of the products, it was not successfully established until the late 'twenties. Wood pulp for the manufacture of viscose rayon is imported from Canada and the Scandinavian countries, via Dunkirk and Rouen, thence distributed mainly by waterway. The raw material for acetate rayon is cotton *linters* (the short fibres removed by the carding machines and frequently known as 'waste' or *bourre du coton*); Havre is the main entrepot. The acetate variety was first used during the war of 1914-18 for coating aeroplane wings, and it has come to be more extensively employed since 1920, although the costs of production are about 15% higher than that of viscose, due partly to the higher price of the raw material and partly to the loss of acetone during processing. *Rhodiaceta*, a company

controlled by the *C.T.A.* and the powerful *Rhone-Poulenc* chemical combine, is the most important acetate rayon producer. Some four-fifths of the French rayon output for 1938 was of the viscose variety, while the rest was almost entirely of the acetate kind. Technically, the acetate process is the simpler, but viscose rayon products are on the whole of higher quality. The cotton and rayon industries have in recent years become closely associated, owing to the possibility of mixing the two fibres; this also applies to the fabrication of wool.

The location of the twenty-three rayon factories in use in France during 1938 is shown on Fig. 85. At first, rayon was produced in factories which had been converted for that purpose, e.g. the earlier factory at Besançon, those at Izieux, Givet, Valence and Argenteuil. Between 1920 and 1929, factories especially designed for rayon manufacture were set up, e.g. at Albi, St Aubin, St Just-des-Marais (near Beauvais), and Besançon. The largest factory is that at Vaux-en-Velin, east of Lyons, built in 1929. In the planning of modern factories, there has been an attempt to form a complete unit of the chemical and textile sections, although they usually remain slightly separated from each other.

The distribution of the rayon factories has been governed by a variety of considerations, more especially easy access to coal and ample water supplies. The presence of skilled labour, however, seems to have been a major factor where the chemical and textile works were grouped together, thus at Izieux, St Chamond and Vals there were silk industry specialists. But there has been a more recent tendency to employ a greater amount of unskilled labour. At places where male labour has been absorbed into neighbouring heavy industries (e.g. at Givet, Valenciennes, Grenoble, Colmar and Albi), the majority of the workers are women. Labour problems have often made it difficult to establish the rayon industry (both fibre and textile) at flourishing textile centres—thus there are factories at Rouen, Arques, and Colmar, but not at Flers, Elbeuf and Mulhouse. On the other hand, a depression in the textile industry, with the consequent releasing of labour, has occasionally led to the opening of rayon factories in certain areas—for example at Calais (by an English firm) and at Amiens.

More than two-thirds of the total French output of rayon is used in France. The Lyons area absorbs about one-third of this output, the St Etienne-St Chamond-Izieux centre about one-fifth; the rest is distributed mainly to Eastern France (the Vosges-Mulhouse area),

to the Nord and to Troyes. Since transport costs are not heavy, rayon supplies are easily sent from the manufacturing areas to other textile centres; thus considerable quantities go from Grenoble to Troyes and from Argenteuil to Lyons.

Fig. 85. The French rayon industry, 1938

PREFACE

IN 1915 a Geographical Section was formed in the Naval Intelligence Division of the Admiralty to write Geographical Handbooks on various parts of the world. The purpose of these handbooks was to supply, by scientific research and skilled arrangement, material for the discussion of naval, military, and political problems, as distinct from the examination of the problems themselves. Many distinguished collaborators assisted in their production, and by the end of 1918 upwards of fifty volumes had been produced in Handbook and Manual form, as well as numerous short-term geographical reports. The demand for these books increased rapidly with each new issue, and they acquired a high reputation for accuracy and impartiality; They are now to be found in Service Establishments and Embassies" throughout the world, and in the early years after the last war were much used by the League of Nations.

The old Handbooks have been extensively used in the present war, and experience has disclosed both their value and their limitations. On the one hand they have proved, beyond all question, how greatly the work of the fighting services and of Government Departments is facilitated if countries of strategic or political importance are covered by handbooks which deal, in a convenient and easily digested form, with their geography, ethnology, administration, and resources. On the other hand, it has become apparent that something more is needed to meet present-day requirements. The old series does not cover many of the countries closely affected by the present war (e.g. Germany, France, Poland, Spain, Portugal, to name only a few); its books are somewhat uneven in quality, and they are inadequately equipped with maps, diagrams, and photographic illustrations.

The present series of Handbooks, while owing its inspiration largely to the former series, is in no sense an attempt to revise or re-edit that series. It is an entirely new set of books, produced in the Naval Intelligence Division by trained geographers drawn largely from the Universities, and working at sub-centres established at Oxford and Cambridge, and is printed by the Oxford and Cambridge University Presses. The books follow, in general, a uniform scheme, though minor modifications will be found in particular cases; and they are furnished with numerous maps and illustrations. At the present time books covering over thirty-five countries are in course

of preparation, and this list will be substantially extended by the end of 1942.

The purpose of the books is primarily naval. They are designed first to provide, for the use of Commanding Officers, information in a comprehensive and convenient form about countries which they may be called upon to visit, not only in war but in peace-time; secondly, to maintain the high standard of education in the Navy and, by supplying officers with material for lectures to naval personnel ashore and afloat, to ensure for all ranks that visits to a new country shall be both interesting and profitable.

Their contents are, however, by no means confined to matters of purely naval interest. For many purposes (e.g. history, administration, resources, communications, etc.) countries must necessarily be treated as a whole, and no attempt is made to limit their treatment exclusively to coastal zones. It is hoped therefore that the Army, the Royal Air Force, and other Government Departments (many of whom have given great assistance in the production of the series) will find these Handbooks even more valuable than their predecessors proved to be both during and after the war of 1914-18.

This volume has been prepared for the Naval Intelligence Division at the Cambridge sub-centre (Director, Mr J. M. Wordie; General Editor, Dr H. C. Darby). It has been written by Mr S. H. Beaver, Mr G. R. Crone, Dr H. C. Darby, Mr I. L. Foster, Mr F. J. Monkhouse, Mr F. W. Morgan, and Dr Hilda Ormsby. The maps and diagrams have been executed by Miss Margaret Alexander, Mr D. Baldwin, Mr A. O. Cole and Miss K. S. A. Froggatt.

J. H. GODFREY

Director of Naval Intelligence

INTRODUCTION

General Features

The population of France in 1936 was 41,907,000, and the mean density over the whole country 76 per sq. km., or 197 per sq. mile. The following table summarizes the principal features of the population of France and her neighbours:

	Population	Area in sq. km.	Density per sq. km.	No. of cities over 100,000
France (1936)	41,907,000	551,000	76	17
United Kingdom (1937)	47,387,000	244,000	194	57
Germany* (1938)	67,500,000	469,000	144	58
Italy (1939)	44,394,000	310,000	143	23
Belgium (1937)	8,361,000	30,000	278	4

* Territory of 1933.

From *Statistical Yearbook of the League of Nations*, 1938-9, p. 18 (Geneva, 1939).

The density of population in France is clearly a low one compared with that in neighbouring countries. It is due largely to the feeble development of urban centres in comparison with that in Great Britain and Germany. Not merely are there relatively few cities with 100,000 inhabitants, but there are only four of over 250,000, as against sixteen in Great Britain. Great as is the dominance of Paris over other

French cities, it represents a comparatively modest part of the population of the whole country. In Greater Paris live 6,300,000 people, whereas in England and Wales, with a population approximately equal to that of France, Greater London can be regarded as holding over **10,000,000**.

In 1936, 21,972,000 people were classified as urban dwellers and 19,935,000 rural, i.e. the urban population was 52% of the total. In contrast, the urban population in Germany and Austria amounts to 66% of the total, and in Great Britain to 80%. But low as is the French figure, it exaggerates the proportion of the population classed as urban, for the classification includes as urban any commune in which the agglomerated or grouped population reaches 2,000, and thus all the little market centres of the countryside and even many large villages are counted as urban.

The fact that Italy, a country which is urbanized to only a moderate degree, has a mean density of population almost double that of France suggests that the French rural population is not a dense one for western Europe. The density of population in her most populous countrysides is considerably below the corresponding figures for neighbouring countries, for there is, by comparison, a smaller farming population actually employed upon agricultural land. In 1931, for example, in rural France 7,704,000 persons were working in agriculture upon 347,040 sq. km. of land used for agricultural purposes (i.e. cultivated land, meadow, and pasture), a density of 22 persons occupied per sq. km. The corresponding figure for Italy was 41, for Germany 32.5, and for Belgium 33. It must be remembered that figures of agricultural density for the whole country conceal the fact that an appreciable section of the French agricultural population is engaged in vine-growing, which is intensive, apart from that section employed in growing fruit and market-garden produce, so that the remaining rural population is inevitably thin.

Occupation Groups

The latest year for which detailed returns of the numbers employed in different occupations is available is 1931, when the total occupied population amounted to 21.6 millions, out of a population of 41.2 millions. The number was, broadly speaking, equally divided between three main categories: (1) agriculture together with forestry and fishing; (2) mining and manufacturing; (3) the distributive and other occupations. This fact illustrates clearly enough the balanced nature of the French economy.

Numbers employed, by category of industry

1931 (in thousands)

	Total		Men	Women	Group total
	Number	%			
Fishing	667	0'3	63'4	3'3	7,704'1
Forestry	58'4	0'2	547	3'7	
Agriculture	7,579'0	35'6	4,392'4	3,186'6	6,402'3
Mining and quarrying	440'7	20	429'3	11'4	
Manufacturing	5,951'6	27'5	3,850'8	2,100'8	
Building	886'1	4'1	874'4	11'7	
Transport	1,069'3	49	9347	134'6	7,515'4
Commerce: Wholesale and retail trade, banking, etc. }	2,695'4	124	1,5382	1,1572	
Entertainment }					
Professions	657'8	3'0	332'6	325'1	7168
Domestic and personal service	893 4	4'1	1766	7168	
Public services	1,313'4	60	1,064 4	249'0	
Total	21,6118		13,7115	7,9002	

From *Annuaire Statistique*, 1938, pp. 104-5 (Paris, 1939).

Detailed comparisons with other countries are not easily made owing to differences in the methods of classifying various occupations. Certain broad differences between France and England and Wales stand out, however. In 1931, although the population of France was greater by only 1·9 millions, the occupied population was greater by 2·8 millions, mainly owing to the large number of women employed in French agriculture. The most striking difference lay in the numbers engaged in agriculture, which were greater in France by 6·5 millions. In mining and manufactures the numbers in England and Wales exceeded those in France by nearly 2 millions: mining and quarrying by 0·5 million, and manufactures by 1·5 millions.

Of the distributive and other occupations, the numbers engaged in England and Wales are greater by about 1·7 millions. In the two countries the numbers engaged in building and in the professions differ very little; in England the numbers engaged in transport are greater, and in trade and commerce considerably greater. The chief difference between the two countries, however, lies in the remaining categories. In England the number of people engaged in domestic and personal service is more than twice the number so engaged in France; the number of employees in public services, in France, on the other hand, is much greater than in England. Such comparisons must not be pushed too far, however, owing to differences in methods of categorization between the census returns of the two countries.

In France, as elsewhere, occupational groupings are subject to change. For a variety of reasons, the census of 1906 offers the most convenient comparison with the census of 1931. In the quarter of a century between the two censuses the numbers of the occupied population increased by 661,000, an increase almost entirely confined to men. This figure, however, conceals very great changes in detail, which have modified the economy of France in no small degree. Agriculture lost 1,350,000 in the numbers employed, the manufacture of clothing 550,000, and domestic and personal service over 100,000. The greatest gains were registered in the metal industries—782,000; most industries, however, and all the service occupations, increased their labour forces. Most of these changes reflect such widespread tendencies as the movement from the land, and the expansion of the motor and electrical industries.

Changes in Occupation Groups, 1906-31

DISTRIBUTION OF POPULATION

Several main features emerge from a study of the map of population distribution. (1) A number of thinly populated areas stand out, of which four are clearly to be expected—the Alps, the forested Landes,

the narrow belt of the high Pyrenees, and the southern parts of the Central Massif. Population here is below 20 to the sq. km., and comparable to that of Dartmoor or the Welsh mountains. Other regions of low density, however, are all distant from high mountains and fairly near Paris, appearing in some measure to insulate it from the east, south and west. One lies between Paris and Bourges; another, the smallest, lies west of Paris; the third, and largest, consists

Fig. 1. The distribution of population, 1931

Based on the *Atlas de France*, Plates 72-75 (Paris, n.d.).

of the Champagne region and is roughly half-way to the eastern frontier, suggesting a considerable separation between the capital and the eastern regions prior to the development of rapid transport, and forming an interesting commentary on the evolution of the French state. It is a situation entirely different from that existing for centuries in the well-peopled English plain. (2) There is a broad belt of population with a density of 20-60 per sq. km., which extends, without any substantial interruption, from Normandy almost to the Pyrenees.

This is a purely rural population, comparable in density to that found in the central and western parts of Devonshire. Only three regions possess any dense rural populations on a considerable scale—the plain of Alsace, Brittany, and the wine district of Languedoc; smaller and often discontinuous areas are found along the lower valleys of the Rhone, Garonne, and Loire. (3) There are few areas of dense urban agglomerations and associated semi-urban populations which are so common in England; only two stand out—the Paris region and the northern coalfield. The others are smaller, like those of the ports, or else composite and spread over some distance, like the Lorraine industrial centres, the cities of Alsace or the Lyons-St Etienne group. A prominent feature of these densely peopled areas is their location on or near the land or sea frontiers, especially the eastern frontier.

In the following detailed account the regions described are, broadly speaking, those which appear in the physical description, vol. 1 of this Handbook (pp. 6-7). It is impossible, however, to keep entirely to the physical regions.

(1) *Brittany* (Fig. 2)

A prominent and well-known feature of the distribution of population in Brittany is the relative concentration in the coastal zone, or the 'Armor'. This concentration is not a regular belt of dense population but rather a series of small hinterlands extending around each of the many Breton ports. The interior, or 'Arcoet', is only moderately peopled, and possesses only three towns of any size—Rennes (98,000), the university centre and former capital of Brittany, Fougères (20,000), towards the east, and Pontivy (6,000), to the west.

Generally speaking, the soils of the coastal regions are not more fertile than those of the interior; proximity to the sea coast, however, has enabled the cultivators from time immemorial to utilize shelly sands to lighten the clays and seaweed to dress the sandy soils. The improved agriculture possible is reflected in the greater amount of wheat grown in these regions compared with the buckwheat of the interior. During the last century or so these agricultural possibilities have been extended, for with the demand for market-garden produce, both in England and in France, the mild climate and sheltered aspect of many of these little coastal areas have been utilized in the development of a considerable market-gardening industry. The many small ports which serve this industry themselves provide a market, as do the larger ports of Brest and Lorient.

This coastal zone also derives some of its attraction from the

proximity of the sea itself, although this factor has frequently been over-emphasized. Fishermen proper are comparatively rare, being found mostly at St Malo and Paimpol on the north coast and at He de Groix and Lorient on the south. Elsewhere, fishing is usually the part-time occupation of a man who has a little land or some other means of livelihood on shore, and the proportion of time spent on fishing as against farming varies considerably. Subsidiary industries such as fish canning offer other means of livelihood in several of the small towns; the pensions received by the male population liable to the *circonscription maritime* and the tourist traffic provide yet other sources of income. This dense population has given rise to the traditional notion of the coastal zone being a *ceinture d'oree* or 'golden girdle' around the peninsula. The concentration of population is undeniable, but it is wrong to assume that this means also a concentration of wealth. In some of the most productive agricultural areas, like those around Roscoff and Plougastel, there is often an intense subdivision of the available land which means a small share of the returns for many individuals. And, further, between some of these richer districts along the coast lie others which are less rich than the interior where, in a number of areas, improved methods of stock raising and cider-apple production have transformed the standard of living. The greater density of population in Armor is due to a higher birth-rate and not to any attraction of an Eldorado, for emigration from the interior is not to Armor but elsewhere. Subsidiary industries may have exploited cheap labour in the past rather than have brought wealth, for at the beginning of this century several investigators commented on the extreme poverty of workers in the sardine-packing factories. Further, the high value of land in the Armor is due partly to the competition for its possession among an overcrowded farming population.

The interior of Brittany is very different, with a rural population of 40-60 per sq. km. against 150-200 in Armor. The density here is low only in comparison with the coast, for the same figure applies to the greater part of rural France. The population has lived for centuries by means of low-grade tillage, which in the last generation has seen much conversion to fodder production for cattle rearing. This is the region which provides the many Breton emigrants who have gone to neighbouring towns like Rennes, Nantes and Angers, to Paris, and recently to rural areas. The interior of Brittany is the *bocage* countryside *par excellence*, with enclosed fields everywhere except on the unreclaimed *landes*, with settlement widely spread about a multi-

plicity of roads; with farms and hamlets on the sides of ridges, below windswept hill tops and above damp valley bottoms.

Most of the towns of the peninsula lie on or near the coast. On the south coast the largest are Vannes (24,000), the naval base of Lorient (46,000), Quimper (19,000) and Douarnenez (10,000). In the extreme west, Brest (79,000) and the two adjoining towns of Lambazellec (19,000) and St Pierre Quilbignon (14,000) form a considerable centre of population. Along the north coast are Morlaix (14,000), St Briec (31,000), and St Malo-St Servan (26,000), with Dinan (12,000) a short distance inland.

The same moderate and widely spread population continues eastwards through the border department of Ille-et-Vilaine into the region of Maine and southern Normandy. The most easterly part of the Armorican plateau carries a thinner population where the forests of the 'march', like Marchenoir, formerly stood. In the centre of Maine around Le Mans is some concentration of settlement, as again on the warmer calcareous soils in the south towards Touraine, in the valley of the Loire (a tributary of the Loire). To the north, on the borders of Normandy, is the most extensive area of low density to be found anywhere in north-western France, in the broken country of the Hills of Normandy and of Perche, and indeed this density does not increase very much to within a short distance of Paris itself. Western Normandy, in the Bocage Normand and in Co ten tin, seems to be, in density of population, an extension of the Breton Arcoet, but the west coast of the peninsula is no counterpart to the *ceintare doree*, and there is only one port, Granville (10,000). The modern port of Cherbourg (39,000) lies at the extremity of the Cotentin peninsula, and has not developed any fringe of population around itself. The largest town in western Normandy is Caen (61,000), which is the centre of a well-populated district of villages on the limestone soils of the area; nearby are St Lo (12,000) and Lisieux (16,000). Southwards towards the Loire, in Maine, lie Le Mans (84,000), the important military centre, and Laval (28,000).

Fig. 2. The distribution of population in north-western France, 1931

Based on the *Atlas de France*, Plate 72 (Paris, n.d.).

This map, like Figs. 3, 4, 5, 6, 7, 8, and 9, is constructed on the basis of communes. A, Angers; Al, Alencon; B, Brest; Bl, Blois; C, Caen; Ca, Chateaudun; Ch, Cherbourg; Cha, Chateaulin; Chr, Chartres; D, Douarnenez; Dx, Dreux; E, Elbeuf; Ev, Evreux; F, Fecamp; Fr, Fougeres; G, Granville; H, Havre; Li, Lannion; La, Laval; L, Lorient; Lv, Louviers; LeM, Le Mans; M, Morlaix; N, Nantes; Nr, Nogent-le-Rotrou; P, Paimpol; Po, Pontivy; Q, Quimper; Rn, Rennes; R, Rouen; Re, Roscoff; S, Saumur; StB, St Briec; StM, St Malo; StN, St Nazaire; T, Tours; V, Vannes; Vi, Vitre.

(2) *The Paris Basin* (Fig. 3)

Like Picardy which it adjoins, eastern Normandy, in the Pays de Caux and Pays de Bray, supports an active and numerous agricultural population, in a variety of village and hamlet types, but Fig. 3 clearly shows the effects of urban settlement. Around Havre (164,000, agglomeration 190,000) lie several subsidiary towns; garden cities are becoming important along the Seine, upstream and around the mouth, with such activities as decentralized engineering industries and petroleum refining, e.g. Port Jerome. On a very small scale, a similar development is taking place near Dieppe (Dieppe-Neuville, 29,000), where the little town of Arques has industries such as rayon manufacture; its population of only 2,500 is an indication of the decentralized nature of the factory village that is appearing in the Seine-Inferieure Departement. Rouen lies in an irregular grouping of urban settlements: the city itself has 123,000 inhabitants, Sotteville the bridgehead town has 27,000, but the population of the agglomeration of these two, together with contiguous towns, is 240,000. The straggling town life of the area is a very old survival and is largely a reflexion of the long-established Norman textile industry; nearby is another centre, Elbeuf (17,000, or 35,000 with adjoining districts). To the south, in the valley of the Iton, lie Louviers (10,000) and Evreux (20,000).

In the centre of the Paris Basin lies the great concentration of population in and around the capital (see also pp. 82-101). The city itself, together with the adjoining suburbs, make up the department of the Seine. This area represents present-day Paris and holds a population of 4,963,000. Outside the Seine department lie adjoining towns, like Rueil Malmaison and Aulnay-sous-Bois, which make up Greater Paris, while farther out are many more residential and manufacturing towns which are satellites of the capital, like Argenteuil and Versailles. The department of Seine-et-Oise, which completely surrounds the Seine department, contains the greater part of this population. In 1936, with 1,413,000 inhabitants, it was the third most populous department in France, being exceeded only by the Seine and the Nord. Seine-et-Marne, the department lying to the east, with 409,000 inhabitants, contains most of the remaining satellite population. A small overflow extends northwards into the southern part of the Oise department, chiefly around the important railway centre of Creil (11,000).

The entire area of urban and semi-urban population, made up by

Paris itself, the suburbs and the satellites, may be described as a quadrilateral extending over about 100 km. from Mantes in the west to Meaux in the east, and over the same distance from Creil in the north to Etampes in the south. Beyond these extreme limits, however, population rapidly diminishes to rural densities, and in the east of the Seine-et-Marne department is very thin. Outer suburban railway services reach farther to the east and south as far as Chateau Thierry and Montargis (14,000), and are responsible for outlying groups of denser population. In recent years, too, the main roads have allowed the growth of radiating lines of newer settlements.

The departments of Seine-et-Oise and Seine-et-Marne contain forty-two administrative towns of over 10,000 inhabitants. Some of these are spreading residential areas with little individuality, others are old towns and villages which have received a new access of population through the growth of the capital. None reaches any great size, for the largest is Versailles (74,000), and the majority do not exceed 15,000.

The distribution of these satellite towns is most uneven; nearly all lie to the east or west, few to the north or south. Immediately to the east of Paris lie nine towns, mainly residential, of which the largest is Aulnay-sous-Bois (32,000). To the south, some distance up the Seine, five towns lie near each other, of which the largest is Villeneuve-St Georges (21,000). Engineering and metal industries have developed here considerably in recent years. To the west, however, lies the principal group of satellite towns, numbering twenty-one. The largest are Versailles (74,000) and Argenteuil (59,000), while Maisons-Lafitte (13,000) and Sartrouville (17,000), lying on opposite sides of a road and rail crossing of the Seine, form the third largest centre of population. Following the expansion of motor, aircraft and other industries in recent decades, a number of former villages have expanded to the size of small towns. These satellites on the western side of Paris lie mainly in two groups—within the bend of the Seine below Argenteuil, and between Versailles and the capital.

The population of these departments may be analysed as follows:

	Population in thousands			Towns			
	Total	Rural	Urban	10-15,000	15-25,000	25-50,000	Over 50,000
Seine-et-Oise	1,413	345	1,068	25	9	2	2
Seine-et-Marne	409	255	154	2	2		

Beyond the Paris region rural France is soon reached. To the west, in the countrysides of Hurepoix and the Thimerais, there is a thinning out of the density; a belt of more active agriculture reaches towards the Loire through the cathedral city of Chartres (27,000) and Chateaudun (6,000). South of Paris lie the extensive and famous wheatlands of Beauce, but farming is not very intensive and the moderate population is found in villages or large farms usually near a well or other water supply. At the elbow of the Loire stands Orleans (73,000). The rich alluvial margins and terraces introduce a belt of dense agricultural settlement, based largely on viticulture. This strip forms a sharp contrast to the considerable forest in the sands immediately north of Orleans and to the extensive forest region of the Sologne to the south, where population is very thin on the lake-studded clay. Eastwards, on either side of the Yonne, is the irregularly spaced and less numerous population of the Senonais, Gatinais and Pays d'Othe. The chief towns are Sens (18,000) and Montargis (14,000).

East and north-east of Paris, on the Tertiary plateaux of Brie, V'alois and Soissonais, lies a semicircle of active agricultural population, grouped largely in villages though with many scattered farms, especially in Brie, where they form a distinct landscape; the distribution is irregular owing to the diversified background of loam-covered plateau and river valley. Here in the northern apex of these plateaux is an area for long one of the most wealthy in France, around Noyon, Laon (20,000), Reims and Soissons (20,000), where the varied outcrops of sands and limestones and the limon cappings have long provided fertile arable land, as well as timber and building stone. In the easterly extension of these plateaux an outstanding thickening of population is seen in the Champagne wine district, where many

Fig. 3. The distribution of population in the Paris Basin, 1931

A, Amiens; Al, Alencon; Av, Avallon; Ax, Auxerre; B, Beauvais; Bl, Blois; Br, Bar-le-Duc; C, Caen; Ca, CMteaudun; Ch, CMLons-sur-Marne; Cm, Cornmercy; Cn, Conflans; Co, Corbeil; Cp, Compiègne; Cr, Creil; Cs, Cosne; Ct, Chaumont; Chr, Chartres; CM, Charleville-Mezieres; Dx, Dreux; Di, Dieppe; D, Dijon; E, Elbeuf; Ep, Epernay; Et, Etampes; Ev, Evreux; F, Fecamp; Fe, La Fere; Fo, Fourmies; G, Gray; Hn, Hirson; J, Joigny; Lu, Lumes; La, Laval; Ln, Laon; Ls, Langres; Lo, Longuyon; Lv, Louviers; Lw, Longwy; H, Havre; M, Mantes; Me, Melun; Mo, Montargis; Mx, Meaux; Nr, Nogent-le-Rotrou; O, Orleans; Re, Revin; Rm, Reims; R, Rouen; S, Soissons; Se, Sedan; Sn, Sens; StQ, St Quentin; StD, St Dizier; T, Tours; Te, Le Treport; To, Toul; Tr, Troyes; V, Verdun; Vi, Vitry-le-Francois.

villages lie on the slopes of the plateau, and where agriculture also meets the local demand of the urban populations of Reims (117,000) and Epernay (20,000). Reims is an important provincial city, with its market and ecclesiastical functions as well as a long-established textile industry now employing 20,000 people. Towards the frontier there is a belt of considerable agricultural population in the heavier soils at the foot of the Ardennes.

To the east, all these traditionally fruitful regions come relatively sharply against the curving belt of the chalk of Champagne *pouilleuse* where a dry subsoil and absence of loam covering involve a decline of cultivation. The density of population changes sharply to a figure of 15 inhabitants to the sq. km. over considerable areas, a density comparable to that of mountain regions. Champagne is a prominent area of sparsity on the population map of France. Settlement is concentrated along the river valleys, and over a large area there are only two towns of any size, Châlons-sur-Marne (35,000) and Troyes (58,000), with its textile and metallurgical industries. Eastwards beyond the chalk lies the narrow arc of humid Champagne, where the fertile Gault clays and intercalated sands form the basis of a larger and much more evenly spread population, although the few towns, such as St Dizier (19,000), all have populations below 20,000. Eastwards, again, is a further arc, of the Jurassic rocks; on the lower ground these carry a fair population, though to the north the belt thins out into the wooded heights of the Argonne, where villages are infrequent. The plateau of the Oolitic limestone is broken up by the rivers, and in detail the population, which is not considerable, is unequally distributed, frequently seeking valleys where marls and clays are exposed. Here again towns are small: Bar-le-Duc (17,000) and Commercy (7,000), together with St Dizier in the Gault region, carry on a small metallurgical industry of long standing, accounting for small areas of denser population. Here, at the Meuse, Lorraine is reached; more to the south the limestone plateau widens, and on the porous soils the villages become infrequent, usually seeking the marls and clays of the valleys. The only town of importance is Chaumont (18,000), on the upper Marne. This region around the headwaters of the Seine and Aube stands out as a large area of scanty population, and separates the Paris Basin from Burgundy.

Along the northern border of the Central Massif is a belt of territory composed of several geological formations where the sedimentary beds of the Paris Basin meet the older rocks of the plateau. Agricultural possibilities vary considerably, and small productive districts, mainly

Plate 1. The *Grande-Place*, Arras

The open cobbled market-place is typical of many French towns. The great square at Arras is the most complete specimen of seventeenth-century Flemish architecture in France; it has been largely restored after sustaining heavy damage during the war of 1914-18.

Plate 2. Lanslebourg in the Arc valley (Savoie)

The town is strung out along the Mt Cenis road on the sunny south-facing slope (*adrei*) of the narrow Arc valley. The north-facing slope (*ubac*) is forested; on the opposite side are cultivated fields and pastures. The hotels only function during the period May-October, when traffic over the Mont Cenis and Iseran passes is possible.

Plate 3. The Chateau of Chambord

This is perhaps the most impressive of all the French chateaux; situated near Blois in the Loire valley, it dates from the early sixteenth century.

along the rivers, are separated from each other by larger thinly inhabited areas, and, surprisingly enough, the agricultural population in these areas of sparsity is thinner than on the plateau to the south. The towns derive some importance from their position on the plateau borders and in a region of varied soils—such are Vierzon-Ville, -Forges and -Village (26,000), Chateauroux (28,000), Issoudun (11,000) and Nevers (34,000). In these towns, as in Bourges, a variety of metal industries are carried on. Bourges (49,000) is an important centre of communications, with engineering and other industries.

(3) *Northern France* (Fig. 4)

Northern France is clearly dominated by the industrial region of the coalfield. The department of the Nord supports a population of 2,022,000 and the Pas-de-Calais 1,179,000. Here occurs an example of that landscape of spreading towns and cities so often found in Great Britain. The industrial population is concentrated in three main groups: (1) the northern area near the Belgian frontier with the cities of Roubaix-Tourcoing and Lille; (2) the central arc of the coalfield itself, stretching from east to west; (3) more detached towns to the south of the coalfield.

In the north, only 5 km. from the Belgian frontier, lies Tourcoing (78,000), hardly to be distinguished from Roubaix (107,000). Eastwards from Roubaix, its satellite of Wattrelos (31,000) reaches almost to the frontier. The centre of Lille (200,000) is only 11 km. from the centre of Roubaix in a south-westerly direction, and the intervening country is largely occupied by three satellite towns. Lille is the seat of textile, chemical, metallurgical and engineering industries and is the commercial metropolis of northern France (see pp. 408-10). It is closely packed within restricted administrative limits, so that it stands only seventh among French cities. Around it, however, and virtually contiguous, lie nine administrative towns with populations ranging from 10,000 to 21,000, and many smaller urban areas. Altogether, Lille, Roubaix, Tourcoing and their tributary towns and suburbs contain nearly 750,000 people. In contrast, Armentieres (24,000) stands isolated, a short distance to the north-west.

A few kilometres to the south of Lille is Carvin (19,000), and with Lens (33,000) and Douai (42,000), the centre of the coalfield is reached. Throughout the entire length of the mining belt there is no great city, although there are twenty-three administrative towns with populations exceeding 10,000, from Valenciennes (42,000)—in the east to Bruay-en-Artois (32,000) in the west, of which Valenciennes is the

largest. In such a region of mines and factories, however, administrative boundaries are very imperfectly related to the formless urban settlements and mining villages.

Bordering the coalfield to the south, but separated from it, are the more isolated textile centres of Arras (34,000), Cambrai (29,000) and Caudry (13,000); farther east, near the Belgian frontier, lies Maubeuge (23,000), with metallurgical industries. To the south-east is a more isolated centre of population: Fourmies (14,000), with the important railway centre of Hirson (11,000) nearby, and farther east again, on the Meuse, is Charleville-Mezieres (31,000) at a meeting point of several railways and the seat of a variety of metallurgical industries. Higher up the river lies Sedan (18,000).

Beyond the western limits of the coalfield lie two towns which mark a transition to the farms of Flanders—St Omer (18,000) and Hazebrouck (15,000), which are textile manufacturing towns as well as market centres. In the Flanders agricultural area farming is intensive to meet urban demands. It is a countryside of many scattered farms, at no great distance from each other. Near the reclaimed coastal marshes the farms are often strung in lines along the dykes. The coastline of northern France is the site of no large centre of population, although Calais (67,000) and Boulogne (52,000) are actually the largest administrative towns in the department of the Pas-de-Calais. Dunkirk (31,000) carries on few of the industries so often found in a great port, and hence its population is comparatively small. Virtually adjoining it, however, lies four small towns—St Pol-sur-Mer (13,000), Malo-les-Bains (11,000), Coudekerque-Branche (13,000)

Fig. 4. The distribution of population in northern France, 1931

and Rosendael (17,000), and the population of 'Greater Dunkirk' reaches 95,000.

Southwards from the industrial region is an area which, as might be expected, has frequent patches of denser population. Besides the two ancient cities of Amiens (94,000) and St Quentin (49,000), with their textile industries, are smaller centres of population created largely by the heavy road, rail and canal traffic between the north and Paris, especially along the Oise canal, one such centre being Chauny-Tergnier-La Fere, at the junction of the Oise and St Quentin canals, although there is no pronounced belt of population. The agricultural population, save for limited areas, is denser than in much of France, for farming is often intensive, both on the clay-with-flints of Picardy and neighbouring parts of Normandy and on the *limon* of eastern Artois and Picardy. The urban demand for milk and market-garden produce is considerable, and is augmented by that from the Channel ports and small resorts. In the Santerre, Vermandois and Cambresis the villages are hardly 3 km. apart. They lie as a rule on the low plateaux, drawing water from the surface-soil layers, and in the valleys or near water sources lie towns, mills and factories. Though the geological foundation of this region is very similar to the chalk of Champagne, settlement is much more free in its location owing to the considerable thickness of surface soil. Southwards, towards Paris, the two largest towns are Beauvais (19,000) and Compiègne (19,000).

(4) *Eastern France* (Fig. 5)

In France east of the Meuse there is a considerable population, amounting to 3,000,000, and showing great variations in its distribution. Between Meuse and Moselle is a moderate agricultural density; east of the Moselle this increases, except for small areas, to a maximum in the plain of Alsace bordering the Rhine. There is a productive and long-established agriculture. The extensive, high and level plains of Lorraine, crossed by northward-flowing rivers and the eastward-facing escarpments or 'Cotes', offer a great variety of resources to its inhabitants—wood, water, and soils suitable for arable land, orchard or meadow. In general the soils are heavy but well repay the great efforts necessary for their cultivation. In the vales the villages are numerous, often seeking an elevated site, so as to avoid damp clay, and along the cotes they stand half-way up. The natural subdivisions of the region, resulting from the cutting through of the cotes by the originally consequent streams, together with the traffic of ages between

the Paris Basin and the Rhine, favoured the development of a number of towns, like Verdun (19,000), Toul (13,000), Luneville and Metz. In Alsace agriculture offers rather greater contrasts than in Lorraine. On the western and gentler slopes of the Vosges a comparatively dense population is widespread in the south; here the soils derived from granite are more hospitable and the original forest cover has been extensively cleared. The lower sandstone Vosges to the north carry a smaller population and retain more of the forest. Rural settlement on the western slopes is considerably scattered; on the eastern slopes single farms are found only at the higher altitudes, and lower down villages become the rule. The elevated loess belt or apron at the foot of the Vosges carries the greatest population; distribution is more irregular near the 111 and the Rhine owing to the occurrence of coarse gravel and of swampy ground, and settlement sites are more selective. Between Mulhouse and Belfort, at the south end of the plain, lies the Sundgau, and among the pebble deposits on this terrace the agricultural population is sparser and unevenly spread. An active town life in Alsace, as in Lorraine, has been long established. On the western slopes of the Vosges, with the help of water power and timber supplies, several small towns early developed small industries, such as textiles and leather, with paper and metal goods later on: such are Saint-Die (20,000), Remiremont (10,000) and Epinal. To the east, each valley opening into the Plain of Alsace has a small town at its foot, while Strasbourg, Colmar and Mulhouse early acquired importance from their location on busy routes, and the two latter developed textile industries; small textile centres extend into the Vosges towards Saint-Die on the western side.

With the nineteenth century came urban expansion, complicated at times by the political changes in the region. Many of the little towns have grown only slowly or even declined: the population of Epinal has fallen from 30,000 (1911) to 28,000 (1936). In the plain of Alsace, Colmar (49,000) and Mulhouse (98,000) are the centres of a large-scale cotton industry. Strasbourg has shown a steady expansion in recent years: the city has 193,000 inhabitants, its neighbour Schiltigheim 22,000, and the whole agglomeration 268,000 (see pp. 337-41). Saverne, near the Saverne gap, remains small; to the north-east is Haguenau (22,000), centre of an agricultural district. Lorraine has experienced both city growth and the appearance of mining villages following the rise of the large-scale metallurgical industries. The chief centre is Nancy, which grew rapidly from 53,000 to 80,000 in 1870-80, reached 120,000 in 1911, and after a relapse has now attained the

Fig. 5

same figure. For about 10 km. above and below on the Meurthe extends a string of industrial towns and villages, and the entire group from Pompey-Frouard to Dombasle has a population of 200,000. Ten kilometres farther upstream is Luneville (24,000), with an expanding population based upon engineering industries. In the north, towards the frontier, lie three more diffuse groups: the largest is the Briey-Thionville group of three valleys, totalling 155,000; westwards is the small Longwy mining region; eastwards is the group of small towns dependent upon the Saar coalfield, none of which is very large. Centrally placed among all these populations is Metz (83,000), important mainly for industries related to the agriculture of the surrounding district. A short distance to the south-west of Mulhouse, where the Doubs enters in a southward course, lies a prominent area of industrial population. Belfort (45,000), besides being an important military and railway centre, is the seat of heavy electrical industries. Only 12 km. to the south is Montbéliard (14,000), which carries on a considerable clock-making industry as well as textile and light metal industries. Around it lie several smaller towns, like Audincourt, which are similarly engaged.

(5) *West and South-Western France* (Fig. 6)

From the Loire to the Garonne. Below Orleans the valley of the Loire shows a greater density of population, which is based primarily upon a more intensive agriculture, especially the culture of the vine, and distributed in a series of denser areas rather than in a continuous belt. Settlement sites show considerable variation; villages avoid the lower alluvial stretches liable to flooding, while many single farms lie on or near levees and reclaimed land dating from various periods since the Middle Ages. Each stretch of denser population centres upon one of the Loire towns, which succeed each other at fairly regular

intervals—Blois (26,000), Tours (84,000), Saumur (17,000) and Angers (88,000), the larger of which are important centres of communication. The valley population is largest around Nantes (195,000), being increased both by the demand from the city for agricultural produce and by the outward spread of subsidiary urban settlement; the total population of Nantes and its satellites approaches a quarter of a million. On the south bank of the river stands Reze (13,000). At the mouth of the estuary is the great shipbuilding centre of St Nazaire (43,000).

South of the Loire, between the Central Massif and the sea, the distribution of population calls for little remark. It is an extensive region, devoted entirely to agriculture, in which the southern extension of the Armorican rocks in the Vendee carries a greater density than the sedimentaries around Poitiers; in the Vendee, however, the concentration of population is inland rather than along the coast as in Brittany. Cholet (23,000) and Niort (28,000) are market centres; Poitiers (44,000) derives a rather greater importance from its position on the main route between the Aquitaine and Paris Basins. Farther south the important wine district along the Charente appears as a narrow belt of greater density of population, involving a group of towns: Angouleme (39,000) and Saintes (21,000) are inland centres; Rochefort (29,000) is a minor naval base, and Tonnay-Charente is the port for the Cognac district. A little to the north of the latter is the fishing port of La Rochelle (48,000), which, with its newly developed port of La Pallice, is a competitor of Bordeaux for the trade of western France.

The Aquitaine Basin. The most striking feature of the map of this region is the gap created by the Landes. Here, in an area considerably larger than the whole of Devonshire (800,000 hectares), the presence of sands and the imperfect drainage repel settlement, and make the region one of the most thinly populated in Europe. What settlement there is tends to follow the streams; one thin belt of population lies close to the coast, near the etangs, while another concentrates along

Fig. 6. The distribution of population in south-western France, 1931

the two Leyre rivers; on the landward circumference is a sone of colonization.

In the main part of the basin, of a total population of nearly 3,000,000, nearly half, or 1,200,000, is concentrated in the two departments of Gironde and Dordogne. This dense population along the lower Garonne and lower Dordogne and its tributaries, and along the Gironde estuary, stands out clearly enough on the map. Here a number of famous wine districts lie close to each other, while the urban centres further increase the population of the surrounding countryside. Bordeaux (258,000) has seven smaller towns adjoining—Begles, Cauderan, Talence, Le Bouscat, Merignac, Pessac and Cenon. The populations of these satellites range from 23,000 to 10,000. Down the estuary are Blaye and the oil ports of Pauillac and Bee d'Ambes. In 1936 the city and tributary urban centres contained 400,000 inhabitants. To the east is the small town of Libourne (19,000) on the Dordogne, and beyond, not far from the borders of the Central Massif, are Perigueux (37,000) and Bergerac (19,000). In the Garonne Basin a succession of well-peopled districts follows the river valley to a point beyond Toulouse. Generally speaking, agriculture in this middle zone is more varied and more intensive than towards the fringes of the basin, although tongues of vine growing reach up the lower valleys of the tributaries, and away from the main stream population density is lower.

Towards the Central Massif it diminishes rapidly on meeting the Causses; on the southern side of the basin it continues fairly evenly, spreading out into a broad triangle to the Pyrenean foot-hill zone, except for an island of sparsity on the detritus plateau of Armagnac, near Auch. In the centre of the basin lies the small market centre of Agen (27,000), limited in its development by the existence of two great cities at either end. Urban centres are more widely distributed in the east than in the west. Toulouse (213,000) continues its growth, based as it is upon a variety of factors. It functions as economic capital for the eastern part of the basin as well as for the central Pyrenean region, it commands the Languedoc corridor to the Mediterranean, and it benefits from a strategic location on the electricity grid connecting the Pyrenees and Central Massif. The other towns of this region lie close to the edge of the plateau, and derive some importance from their position at a junction of different types of economic region—Montauban (32,000), Albi (30,000) and Castres (29,000). Albi and Castres, together with the smaller town of Carmaux (10,000), possess industries based upon hydro-electric power from the Central Massif,

Plate 4. Sare (Basses-Pyrenees)

The village comprises a small cluster of houses around the church, with numerous outlying dwellings set in an undulating landscape of enclosed fields. In the background are the Pyrenean foot-hills.

Plate 5. La Grave (Hautes-Alpes)

The village of La Grave (1,482 m. above sea level), a popular tourist centre, is situated on a shoulder about 100 m. above the Romanche valley, which leads to the Col du Lautaret. Above the village are the *alps*, which in summer yield crops of hay and potatoes.

and from the small coalfield at Carmaux. Mazamet (15,000), besides manufacturing woollen goods, is a centre for the cleaning of wool.

(6) *The Central Massif* (Fig. 7)

In this extensive region the main factors affecting the distribution of agricultural population are elevation and soil characteristics. The high plateaux of over 1,000 m. are sparsely populated, while the low plateau of Limousin at 300 m. carries a fairly dense population. In the high Auvergne, however, fertile volcanic soils form the basis of well-peopled villages and a number of small towns at a height of 1,000 m. In the basins of the north-east settlement is not so widespread as might be expected owing to inadequate drainage of heavy soils.

In the west lies the Limousin, composed largely of a low plateau of granitic soils surrounding a high plateau of ancient eruptive rocks. The high ground stands out as an area of sparsity in Fig. 7; here the basis of life is a rather poor agriculture with rye as an important crop and the grazing but not fattening of cattle. On the lower tableland, called locally the 'Besse', the soil is deeper and the climate less harsh. Cereal growing, irrigated meadows, chestnut trees, and the famous Limousin cattle support an active population. The regional capital is Limoges (95,000) with its famous pottery industry. The smaller towns are market centres like Aubusson and Gueret, usually situated near the junction of the high and low tablelands. On the southern border of the main plateau lies Brive (29,000), the market town of a fertile district of Trias rocks, and nearby, on the edge of the plateau, is Tulle (15,000).

To the south of the Brive basin appears an isolated area of low population density, where a considerable extent of Oolitic limestone at a height of from 300 to 500 m. limits the possibilities of human occupation. Fragmentary settlement is found over the limestone plateaux, but the greater part of the population is concentrated in the valleys. This is the region of the 'Little Causses'. In the south-eastern extremity of the Central Massif lies a more pronounced limestone country—the 'Great Causses'. The surface here is often 750-1000 m. high, and forms a stony desert. Sheep rearing supports a scanty population; agricultural settlement is confined to the narrow valleys; where topography and water supply permit, fruitful cultivation is possible in this southern latitude. The area of sparse population extends south-westwards almost to the Gate of Carcassonne over a triangular block of Palaeozoic rocks. Here, however, the valleys are

Fig.7

wider, and form tongues of populated territory alternating with ridges like the Espinouse and Montagne Noire. Towards the south-western edge of the main plateau lie the administrative and market centres of Rodez (18,000) and Millau (16,000), and Decazeville (12,000), centre of a small coalmining centre.

East of the Causses towards the Rhone the area of sparsity is still considerable. Here is the high edge of the Massif, the Cevennes, where altitude is the main factor inimical to any dense settlement. Population increases rapidly, however, as altitude diminishes towards Languedoc. First comes a belt of hamlets in a pastoral zone, then the villages in the chestnut zone, where cultivation increases, and finally the zone of Mediterranean cultivation is reached. A ridge of highland approaching close to the sea, between the river Herault and Montpellier, results in an extension of the area of sparse settlement into the lowland.

Auvergne, the heart of the Central Massif, includes lands of widely varying densities of population. The great area of sparsity in the south-east of the main plateau extends inwards towards the centre through the high mountains of Aubrac and Margeride. Around the two principal massifs of recent lava, the Velay and the Cantal-Dore, population is a little complicated in its distribution. In places elevation is reduced in its effects by the great fertility of the volcanic soils. The 'planaises' or lava plateaux provide excellent pastures which carry more animals than most parts of the Central Massif. Along the edges of the volcanic massifs is a series of valleys in which agriculture supports a considerable population. At the openings of the valleys, especially where the volcanic soils meet the poorer soils of the granite, are a number of little market and fair towns, some no larger than big villages, both around the Cantal and Dore massifs, while on the limits

Fig. 7. The distribution of population in the Central Massif and its borders, 1931

Based on the *Atlas de France*, Plates 74, 75 (Paris, n.d.).

A, Avignon; Ac, Aurillac; Ae, Ales; Al, Albi; An, Autun; Ar, Aries; As, Aubusson; Bd, Brioude; Be, Beaune; Br, Brive; Bs, Bourges; Bz, Beziers; Brs, Brassac; C, Carcassonne; Ca, Castres; Ce, Le Creusot; Cr, Cahors; CI, Chalon-sur-Saone; Cs, Cosne; Cu, Carmaux; Cx, Chateauroux; Cy, Commentry; CF, Clermont-Ferrand; Dz, Decazeville; Fr, Feurs; Fy, Firminy; G, Gueret; Gc, La Grand-Combe; Gv, Givors; I, Issoudun; Is, Issoire; L, Lyons; Lm, Limoges; Ma, Mazamet; Mb, Montauban; Mc, Montlucon; Mm, Montceau-les-Mines; Mn, Macon; Mr, Monteimar; Ms, Moulins; Mt, Montpellier; Nm, Nimes; Nr, Narbonne; Nv, Nevers; Pm, Pamiers; Py, Le Puy; Ra, Roanne; Rm, Riom; Rz, Rodez; Se, Sete; StC, St Chamond; StE, St Etienne; To, Toulouse; Ts, Thiers; Tu, Tulle; Va, Valence; Vc, Vichy; Vn, Vienne; Vz, Vierzon.

of the Cantal are several larger towns, Aurillac (19,000), Mauriac (3,300) and St Flour (5,000).

In the remaining north-eastern part of the Central Massif the population, broadly speaking, attains everywhere a moderate density and there is a considerable urban development. The long tongues of Archaean rocks, trending northward, are lower, and more agriculture is possible, except in the ridge of the Forez, lying between the Loire and Allien. It is mainly the occurrence of sedimentary basins, however, which enables a denser settlement to exist. The principal of these is the Limagne, along the Allier, extending through the Limagne Bourbonnais to the northern edge of the plateau. Population tends to avoid the lowest levels, which are too damp, and concentrates towards the highlands on either side, especially at the foot of the Dore and Puy de Dome. In the east of the Limagne is the old manufacturing centre of Thiers (16,000); on the west lies Clermont-Ferrand, for long functioning as a market centre for the Limagne but rejuvenated in the twentieth century by its rubber and engineering industries (101,000). Nearby is Riom (11,000) and the spa of Vichy (25,000). In the Limagne Bourbonnais stands Moulins (22,000), and some distance to the west, in a small basin, Montlufon (42,000), which has rubber and engineering industries. Commentry (nearly 10,000) is a small mining and engineering centre. The basins along the Loire are more variable in their attractiveness to settlement. The uppermost around Le Puy (21,000) is the most fertile of all owing to the presence of lava downwash from the surrounding volcanic hills. The Bassin de Forez is, in the main, too ill-drained to support much settlement. There is more lower down in the Roannais, and Roanne (41,000) has developed textile industries.

(7) *The Pyrenees* (Fig. 8)

The highest settlements in the Pyrenees are poor hamlets in the pastoral zone. Lower down, at about 1,000 m., are a number of isolated pockets of denser population, in scattered farms and hamlets, and maintained by varied resources of meadows, orchards, patches of arable land, and timber. Small-scale local industries and a few mineral workings have provided a further means of livelihood. In the last 25 years the considerable development of hydro-electricity has contributed to an increase of population in many of the valleys. Some of the factories are located high up near the stations, but there has been a spread of decentralized industry among villages and small towns where the valleys broaden, like Lann&nazan, Marignac and

Fig. 8. The distribution of population in the Pyrenees region, 1931

Based on the *Atlas de France*, Plate 74 (Paris, n.d.).

Al, Albi; Au, Auch; Ba, Bayonne; Bi, Biarritz; Bz, Beziers; Ca, Castres; C, Carcassonne; Dx, Dax; Lo, Lourdes; Mb, Montauban; Ma, Mazamet; Mo, Mont-de-Marsan; Mt, Montpellier; Nr, Narbonne; Pa, Pau; Pm, Pamiers; Pn, Perpignan; Se, Sete; StG, St Gaudens; StJ, St Jean-de-Luz; Ta, Tarbes; To, Toulouse; V, Port-Vendres.

Lavelanet. The population of the Pyrenean region, neglecting the towns of Bayonne and Biarritz at one end and the Perpignan agricultural region at the other, is approximately 900,000.

Thus between the mountains and the plain there is a zone of many small districts in which the density of population is higher than that of the purely agricultural lowland. It is not a belt of population but only a series of units. Each of these takes up a general trend from north to south, at right angles to the Pyrenees, an arrangement which arises from the absence of any big longitudinal valleys such as are found in the Alps; only in the upper Ariege for a short distance is there any great population in a longitudinal valley. The communities in each valley have therefore had more contact with the plain than with each other. The little towns which grew up at the meeting of valley and lowland remained small for this reason—Meaulon, Oloron, Lourdes (11,000), and Foix. Those farther out from the mountains could serve several areas, and thus grew to be larger; such are Pau (40,000), Tarbes (35,000), Pamiers (14,000), and even Toulouse. In the extreme west stand the port of Bayonne (31,000), the resort of Biarritz (21,000), and Anglet (11,000).

(8) *The Rhone-Saone Valley* (Fig. 9)

In the northern part of the Saone valley the vine was formerly important, and the density of population is high for an agricultural district. South of Chalon-sur-Saone the density increases, and many villages lie on the valley floor, while to the west, along the foot of the Cote d'Or and the Beaujolais, viticulture supports a belt of dense population, especially around Beaune. Southwards beyond Bourg, a pronounced area of sparser settlement appears in the boulder clay covered plateau of Dombes. Urban centres in the north are Besançon (65,000) and Dijon (96,000), in the centre Chalon-sur-Saone (33,000), and in the south Bourg (25,000) and Macon (19,000). Nearby are the industrial towns in the extreme north-east of the Central Massif: Montceau-les-Mines (27,000) and the armaments centre of Le Creusot, the latter forming part of an agglomeration with 40,000 inhabitants.

Lyons, the third city of France, has spread widely beyond its original sites, the hill of Fourviere and the long and narrow strip between the Rhone and Saone, and in recent decades the greatest growth has been to the south-east where Villeurbanne (81,000) is the chief manufacturing suburb. The old and the new parts of the urban area were about equal in population in 1896, when the total population was 497,000. In 1936 the figure was 570,000, although if all contiguous

urban districts be added the total amounts to nearly 800,000. Sixty kilometres to the south-west, just within the Loire Basin, lies St Etienne, with its engineering, hardware, and silk industries; its population is 190,000. To the west lie three tributary towns—Firminy (20,000), Le Chambon-Feugerolles (15,000) and La Ricamarie (10,000); to the east, at intervals along the valley leading to the Rhone and the confluence town of Givors (13,000), is a succession of manufacturing centres, especially St Chamond (15,000) and Rive de Gier (14,000), the population of this long string of settlements being 348,000. The St Etienne district is structurally part of the Central Massif, and its economic development has been largely independent of that of Lyons, but its power demands bring it increasingly within the Alpine hydro-electric system.

From Lyons to the Camargue delta, the Rhone valley is comparatively densely populated, though in irregular fashion. At intervals occur the towns of Vienne (25,000), Valence (36,000), Montelimar (15,000), Avignon (59,000), and Tarascon-Beaucaire (15,000). An intensive and varied agriculture, helped by irrigation, is the basis of this population. The Camargue is an extensive area, by comparison only moderately populated, and much of it is very sparsely settled. The damp and heavy soil yields to agriculture after much reclamation; in the smaller region of the Crau, composed of ancient alluvium, shortage of water demands irrigation. In limited parts of these two districts reclamation in the past half-century has allowed the development of an extensive fruit and market-garden industry, and there has been considerable immigration. Aries (29,000) is a centre for the marketing of agricultural produce.

(9) *The Jura (Fig. 9)*

Eastwards of the plain of Burgundy, the land rises to the high limestone Plateau of the Jura, in which exposures of marl and morainic deposits support a larger population than might have been expected; only one town, Pontarlier (13,000), exists to serve this region. The mountain Jura, however, is two or three times as densely populated as the plateau: between the forest-clad *monts* or anticlines, the valleys, though elevated, are well peopled. Stock rearing and forestry are supplemented by a variety of domestic industries and by watch-making, which are helped by the hydro-electric power available. The southern Jura is more broken and shows considerable contrasts in population density between upland and valley. The uplands support active settlements depending on resources of high meadow and

timber; in the valleys, however, such as the basins of Belley and Saint-Gieaux, agriculture and fruit growing support a more considerable population, and industry is developing upon the basis of ample supplies of hydro-electric power, both near and more distant. Here industry is more concentrated than in the northern and central Jura. The chief towns of the southern Jura are St Claude (11,000) and Oyonnax (10,000), with Lons-le-Saunier (14,000) at the western foot of the plateau.

(10) *The Alps* (Fig. 9)

The Alpine region falls into two main sections. In the north the basins of the Isere and Rhone have an irregularly distributed but by no means inconsiderable population: the two innermost departments, Savoie and Haute-Savoie, have a combined population of 499,000, including only two towns above 20,000. The density on land which can be used in any way, not counting towns of over 3,000, is 40 per sq. km. The southern Alps, however, largely comprising the basin of the Durance, form a thinly populated region: the two innermost departments of Hautes- and Basses-Alpes contain only 175,000 inhabitants, and the density on exploitable land is 17 per sq. km.

The northern region contains a number of valleys in which population congregates, more especially in the west, the line of division being the longitudinal valley running south-west for 200 km. from Mont Blanc to Devoluy and including the Gresivaudan. There has been a steady movement from the higher settlements into this main valley. In this, and in those valleys leading westwards to the Rhone, the traditional foundations of life have been stock raising with some agriculture, helped by local industries such as the glove manufacture around Grenoble. The maximum height at which agriculture is practised is 2,000 m. Eastwards to the frontier pastoralism becomes more and more the basis of existence, and transhumance, or seasonal

migration, more important as a means of extracting every possible gain from the restricted area of soil. Transhumance is particularly well developed in the Tarentaise and Maurienne, and is accompanied by the usual temporary dwellings or chalets. For centuries there has been a winter migration of part of the population to other regions, even as far as Paris; it still takes place, but in the last 50 years has given way more and more to permanent migration.

There is ample choice of sites for settlement open to the small population of the Alpine region. Many villages are found on the alluvial cones of tributary valleys, some being as high as 200 m. above the main valley. Some villages and hamlets lie on the lower benches or glacial shelves; on the higher ones above 1,000 m. or so are found only the temporary dwellings. Here and there a bar crossing a ravine is the site of a village, while at confluences larger villages and small towns are found. It is natural that settlement should take advantage of topographical details to secure a maximum of sunlight, and where valleys trend east and west the northern slope almost always carries most of the dwellings.

The extensive southern region of the Alps is very different. A drier climate and wide extent of bare limestone limit the possibilities of human occupation. The region is the most sparsely populated of the Alps, the least settlement being found in the Pre-Alps. A series of small agricultural districts, sometimes discontinuous, follows the Durance and the lower valleys of its tributaries. The normal decline of density with increase of height is reversed here and the interior valleys are more inhabited than the lower. Gap (13,000) is the largest town in the southern Alpine region; Briançon and Digne have populations below 5,000. Migration from the southern zone of the Alps has been long continued.

The various factors which in the past three-quarters of a century helped to enlarge the foundations of life in the French Alps have all operated with greater effect in the northern region. Tourist traffic and railway development have been more attracted to the north. Domestic industries have been more easily retained and expanded there owing to the greater abundance of accessible hydro-electric power. The latter resource has, of course, resulted in the appearance of large-scale chemical and metallurgical plants, such as Jumieux, Calypso and Ugines, and if these have not resulted in any very direct increase in employment for the people of the region, they have increased the demand for locally produced food supplies. These modern developments are at the base of the steady growth of Grenoble in recent years

Plate 6. Bedous (Basses-Pyrenees)

The larger Pyrenean valleys contain villages at frequent intervals. Bedous lies in the Gave d Aspe, which leads to the Somport pass.

Plate 8. Thiers (Puy-de-D6me)

The town is built in terraces within a meander of the deeply incised river Durolle. It has many ancient stone and timber houses dating from the fifteenth and sixteenth centuries, and has a highly specialized cutlery industry based originally upon local water power.

Plate 9. Aigues-Mortes in the Rhone delta

This extraordinary town lies on the edge of the Etang de la Ville, some 6 km. from the Mediterranean. It is completely surrounded by rectangular ramparts built in the thirteenth century, and is one of the most striking examples of military architecture. See vol. 11, p. 52 of this Handbook.

(96,000). In the northern part of the Alpine region, Chambéry (28,000) is the largest town, lying on a main railway from the Rhone valley to Turin. Annecy (23,000), Aix-les-Bains (13,000), and Thonon (12,000) are resorts.

(11) *The Mediterranean Coastland* (Figs. 7, 8, 9)

Languedoc. This region is characterized by two features: the considerable but irregular belt of dense agricultural population and the number of towns of fair size.

Between the Central Massif and the sea can be found very great contrasts in density. In places there are high and rocky hills with a great extent of limestone, and frequent areas of *garrigue*. Parts of the *garrigue* country around Montpellier are among the most thinly inhabited districts in France, even more than the Alps or the Causses, Where agriculture is possible, however, it can be carried on intensively, and the department of l'Herault, although it contains no great city, has a population density of 83 per sq. km., a figure higher than the density in Normandy. Viticulture and fruit and vegetable growing, largely on a commercial basis, are the foundation for this rural population. Towards the south the mountain range of the Corbieres causes a thinning out of population, but the figure increases again, and in the district behind Perpignan is comparable with the main belt at the foot of the Massif. It is important to notice that this dense population of Languedoc is not a coastal one, though it lies very near to the coast. The sea has exercised a minor effect, and along the 6tangs or lagoons fishing or mercantile population is very restricted.

Demographically, this territory is most interesting, for it has shown much less of the rural decline so common elsewhere. The amount of decline is actually exaggerated a little by the census classification, for where a commune has increased so as to raise the population of the chief settlement above 2,000 it ceases to be classified as rural, though in a number of instances where such an increase has occurred the agricultural activity of the commune has continued. There has been a considerable immigration of foreigners into this territory, much more than in the Aquitaine Basin; they are mostly Spaniards, of whom there were over 80,000 in 1932. Yet the French population has increased more rapidly in the past 50 years than in France as a whole, for, although the birth-rate is not much above that in the Aquitaine Basin, there has been for many years a considerable immigration from other parts of France. Through the agricultural improvements and advance towards intensive and commercial farming in this region,

therefore, a considerable re-distribution of rural population has been taking place.

In the Languedoc agricultural zone there are five towns which have all shared in the expansion of the population as a whole, but not by draining the countryside. While in France from 1872 to 1926 the rural population fell from 69 to 51 %, in the department of l'Herault the fall was only half as great. Nimes has a population of 94,000, and has developed industries owing to its proximity to the Ales coalfield. Nearby is the university city of Montpellier (91,000); Beziers (73,000) carries on textile industries; Sete (37,000), the recently revived port, has a petroleum refinery nearby; Narbonne remains comparatively small with 31,000 inhabitants. Four other towns lie away from the main belt of population: Ales (41,000) and La Grand-Combe (12,000), on the small coalfield at the edge of the Central Massif, are small industrial centres; Perpignan (72,000) is the centre of the Roussillon agricultural region, between the Corbieres and the Pyrenees; Carcassonne (33,000), on the route to Aquitaine, is at the end of the tongue of dense agricultural population extending inland from the Mediterranean.

Provence. Along the coast of Provence lie very limited areas of agricultural population, often close to barren mountains, and the massifs of the Maures and Esterel are among the most thinly peopled regions in France. On the road from Aix, eastwards to Antibes, only a few isolated farms can be seen in 25 km. Cities and towns, however, have developed to a marked degree in recent decades. Toulon (150,000) and La Seyne (27,000), across the roadstead, take a modest place in this expansion. Among the resorts along the Riviera coast, Nice had become, by 1936, the fifth largest city in France with a population of 242,000 (or 272,000 if adjoining resorts be included). In the same year the group of smaller resorts from Cannes to Antibes had a combined population of 102,000. The most interesting feature of expansion in this region, however, has been the growth of Marseilles; at the beginning of this century it had a population of 494,000, while the total of 806,000 in 1931 increased to 914,000 in 1936, mainly through a steady immigration of Midi peasants and of foreigners. The ancient university city of Aix, not far to the north, has a population of only 42,000. Like Aubagne (14,000), east of Marseilles, it engages in some industry. Between Marseilles and Toulon lies La Ciotat (13,000), where there is an important shipbuilding yard.

GROWTH OF POPULATION

The population of France has grown slowly compared with the populations of other countries. In 1800, with over 27 million in habitants, it was the most populous country in Europe, outside Russia, a position which it held until about 1850. After that date the rate of increase slowed down, and the population of France was soon

of the other belligerents in western Europe. Death casualties of France (European troops) were 1,320,000, of Germany 1,827,000, of the United Kingdom 765,000.† These losses were equivalent to 1 in 31 of the total population for France, 1 in 36 for Germany, and 1 in 59 for the United Kingdom. It must be remembered that the war deaths occurred almost entirely among young and middle-aged men, and amounted to 10-5% of these age groups in France, 9-8% in Germany and 5-1 % in the United Kingdom. The natural increase of the population was further affected by the absence of so many men in the armies. It has been estimated that owing to the war the number of births in France was 2,400,000 below the normal number.

The Balance of Births and Deaths

Unlike most other European countries, France has known several years when the number of deaths exceeded the number of births. Between 1854 and 1919 this occurred in seventeen years, and was due mainly to war or epidemic. In the nineteen-year period 1920-38, however, an excess of deaths occurred in five years—1929, 1935-8—and has been due each time to the decline in the number of births.

Excess of Births over Deaths, 1921-38 (in thousands); a deficit is shown by a minus sign

Annual average	France	Germany*	United Kingdom
1921-25	117-2	555'9	352'4
1926-30	59-8	428'7	221'6
1931-35	32	355'6	150'8
1933	18	233	122
1934	43	473	154
1935	- 19	472	150
1936	- 12	483	139
1937	- 12	484	126
1938	-35	546	176

* Including the Saar territory.

(2) *Statistical Year-book of the League of Nations, 1938-9*, pp. 39-41 (Geneva, 1939).

It should be remembered that, in those years in which there has been an excess of births over deaths in France, a high proportion are attributable to the foreign population. During the four years 1925-9, for example, when there was a total excess of births of 240,000, the foreign population was responsible for 130,000.

† The **total** for the **British** Empire was **1,020,000**.

Immigration

In recent years the population of France, with its very low rate of natural increase, has been affected to a considerable extent by the movement of foreigners into the country (see Appendix I).

Natural Increase and Migration, 1922-38, in thousands

	Births	Deaths	Excess of births over deaths	Net immigration
1922	760	688	+ 72	+ 131'3
1923	762	666	+ 95	+ 4-202'9
1924	754	679	+ 75	+ 217'6
1925	770	708	+ 62	+ 121'9
1926	767	713	+ 51	+ 113'4
1927	744	676	+ 66	- 25'6
1928	749	674	+ 70	+ 44'0
1929	730	739	- 9	+140'4
1930	750	649	+ 101	+ 177'8
1931	734	679	+ 55	+ 9'3
1932	722	660	+ 63	- 39'0
1933	679	660	+ 18	+ 25'6
1934	678	634	+ 43	+ 31'5
1935	641	658	- 19	- 10'7
1936	631	642	- 12	- 5'4
1937	617	629	- 12	+ 47'4
1938	612	647	- 35	+ 25'6
			+ 686	+ 1,208'0

From *Annuaire Statistique, 1938 (Resumi Retrospectif)*, Table 1, p. 13 (Paris, 1939).

Thus over this considerable period from 1922 to 1938, the increase in population from immigration exceeded the natural increase by 522,000. The figure should probably be increased to allow for unrecorded immigration: one estimate suggests that during 1920-30 there were 440,000-660,000 unrecorded immigrants, of whom rather less than 70% remained in France—perhaps over 300,000. It will be observed that the totals of immigration have not followed a regular course, for two pronounced maxima can be distinguished. Of the total net immigration of 1,208,000 during 1922-38, 787,000 were accounted for in the period of reconstruction and comparative prosperity which followed the war, and 318,000 in the two years of prosperity, 1929-30, which in France preceded the impact of the world economic depression. For the remaining eight years, therefore, net immigration amounted to only 103,000.

It is clear that immigration has contributed materially to the growth of population in France, whatever allowance may be made for the

effect of variations in trade prosperity. In detail, the contribution made by immigration to population increase over a long period has been estimated as follows:

	Percentage of increase due to net immigration		Percentage of increase due to net immigration
1851-61	13	1891-96	63
1861-66	20	1896-1901	30
1872-76	10	1901-06	43
1876-81	23	1906-11	60
1881-86	27	1921-26	74
1886-91	80	1926-31	76

From J. J. Spengler, *France Faces Depopulation*, pp. 195-6 (Durham, North Carolina, 1938).

Before the war of 1914-18, therefore, in one period of ten years (1886-96) the percentage of increase contributed by immigration was very large.

When absolute figures are examined over a long period, the effects of immigration, compared with the effects of natural increase, are at first sight startling. During the period 1850-1930, for example, net immigration supplied 3'5 millions, against only 2'0 millions from natural increase. During the shorter period 1851-1911, however, immigration contributed over 1 million, compared with 3'9 millions arising from the excess of births over deaths. Much of the discrepancy arises from the effects of the war of 1914-18. In the six years 1914-19, the reduction in the number of births combined with the increases in the number of deaths to produce a total excess of deaths over births of 2,868,000. As there is every reason to believe that there would normally have been, during those years, a total excess of births over deaths, the net loss to the French population exceeded 3 millions. The gain resulting, from immigration may therefore be regarded as offsetting, broadly speaking, the losses which must be ascribed to the war of 1914-18. Thus when the effect of immigration on the growth of the population is considered, it must be remembered that long-period totals of natural increase conceal the exceptional conditions of 1914-19.

Age Groups

The age composition of the population is a product of its past and has a vital bearing upon its future. In general the population of France has not yet 'aged' to the extent sometimes thought, although the tendency is making itself visible. The proportion of children under 1 year in the population in 1931 was practically the same as

the figure for 1851. The 1-19 group has declined and the older age groups have increased their percentages.

Population by Quinquennial Age Groups, as a percentage of Total Population. Based on estimates

	France 1936	England and Wales 1937	Germany* 1937	Nether- lands 1937	Poland 1938
0-4	82	6'8	8'1	95	103
5-9	8'4	7'2	7'2	96	10'9
10-14	8'6	7'8	8'0	9'5	11'4
15-19	5'6	8'1	7'8	9'2	97
20-24	7'3	79	69	8'5	70

65 +	9'8	8'5	7'6	67	
	100'0	100'0	100'0	100'0	100'0

* Including the Saar territory.

From *Statistical Year-book of the League of Nations, 1938-9*, pp. 26-30 (Geneva, 1939)-

It is clear that the age composition of the French population is broadly similar to that of Germany and of England and Wales, and that it differs from the age composition in Poland and the Netherlands in having a smaller proportion of children; it has a much higher proportion of the older ages than occurs in Poland. Among the groups of young and middle ages, the French population is appreciably deficient compared with all countries cited. The position may be summarized as follows:

Population by Big Age Groups

	France 1936	England and Wales 1937	Germany 1937	Nether- lands 1937	Poland 1937
Totals: 0-14	252	218	23'3	286	32'6
15-49	48'9	53'4	54'0	52'1	51'5
50 +	25'9	24'7	22'7	19'3	14'9
Women: 15-49	48'2	53'3	54'0	52'3	52'6

Of the total population men represent 48'3%; neglecting the foreigners in France, however, men represent only 47'3 %.

Two consequences eventually result from an 'ageing' population: (a) An increase in the death-rate, for the higher death-rate of the older people will become increasingly important in its effect upon the total death-rate. It should be remembered that the rate at which the span of life can be lengthened is slowing down, (b) A decrease in the number of births—for the older generations, which are likely to produce fewer children, are now becoming relatively more numerous.

These must now be analysed separately, but whereas the death-rate is a comparatively simple conception which can be dismissed quickly, any account of the birth-rate and its relation to effective reproduction involves a more complicated argument. For this reason the death-rate is considered first, and the birth-rate and its relation to the future growth of population is considered afterwards.

Death-Rates

The crude death-rate in France has declined steadily from nearly 30 per thousand at the beginning of the last century to 15'4 in 1938. It is higher than would be expected, and exceeds the rates prevailing in the countries of north-western Europe and approaches more nearly the rates found in eastern Europe. Since 1801 it has, in every ten-year period, exceeded the rate in England and Wales, but it was not until 1901-10 that it came to exceed the rate in Germany.

Death-Rates, per 1,000 inhabitants

	1932	1933	1934	1935	1936	1937	1938
Yugo-Slavia	19'2	16'9	17'0	16'8	16'0	15'8	—
France	15'8	15'8	15'1	15'7	15'3	15'0	15'4
Poland	15'0	14'2	14'4	14'0	14'2	14'0	13'8
England and Wales	12'0	12'3	11'8	11'7	12'1	12'4	11'6
Germany	10'8	11'2	10'9	11'8	11'8	11'7	11'7
Netherlands	9'0	8'8	8'4	8'7	8'7	8'8	8'5

From *Statistical Year-book of the League of Nations*, 1938-9, p. 44 (Geneva, 1939). For a discussion of the causes of death see vol. 11, pp. 244-9.

If France could reduce the death-rate to that of more favoured countries, a gain of 120,000 lives would be secured each year. Such a gain would have an appreciable effect upon the birth-rate, but would not greatly offset its low figure.

The causes are not easily specified; some authorities ascribe them to the proportion of old people in the population, but this factor can only be a minor effect on the situation: other authorities lay more stress on shortcomings in the administration of health services.

Infantile mortality is appreciably higher than in the neighbouring countries (see vol. 11, p. 243), and the death-rate is also higher for young adult men. The table of mortality by age and sex shows that in France the disparity with Germany and England and Wales is very pronounced for the ages 30-40.

*Mortality by Age and Sex: Specific Rates per 10,000
Inhabitants of each Age Group*

55-59	240	145	229	139	175	138	196	129	130	125

The rates for infants under 1 year are based on 10,000 living births.

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 46-8 (Geneva, 1939).

After allowances have been made for any possible effect of age structure, it appears to be inescapable that in France improvements in welfare and medical services have not succeeded in prolonging the span of life as much as in some other countries of Europe. The average expectation of life is a reflexion of this fact.

Expectation of Life at Birth, in years

		M.	F.
France:	1908-13	48.49	52.41
	1920-23	52.19	56.09
	1928-33	54.30	59.02

	1930-32	58.74	62.88

From *Statistical Year-book of the League of Nations*, 1938-9, pp. 52-4 (Geneva, 1939).

Birth-Rate, Fertility and Reproduction Rates

In France a good deal may yet be done to lengthen the span of life, until a figure comparable with that of some other countries is reached, but clearly the process cannot be continued indefinitely. It is the number and rate of births which are the more important factors for the future. Just as present numbers of a population and its age composition are determined, not by the birth- and death-rates prevailing now, but by the rates which have prevailed during the lifetime of all the generations now living, so will the numbers and age composition of a population at the present time control to a large measure the population of future generations.

The Birth-Rate. The birth-rate, i.e. the number of live births compared with the number of inhabitants, has declined from 32 per 1,000 in 1801-10 to 14·6 in 1938. In the four years preceding 1938 it was lower than the rate in most countries of north-western Europe, and much lower than the birth-rate in eastern Europe.

Birth-Rate per 1,000 Inhabitants

	1932	1933	1934	1935	1936	1937	1938

* Figures in part approximate.

From *Statistical Year-book of the League of Nations, 1938-9*, p. 43 (Geneva, 1939).

Authorities differ in their estimate of the causes of the lowness of the birth-rate in France: some attach a certain importance to the age composition of the population, in that there is a relatively higher proportion of old people who cannot effect natural increase. The percentage of the population formed by women of child-bearing age, however, has not been less favourable to natality than in many other countries of Europe, and a great part of the lowness of the birth-rate must be ascribed to the decline in fertility of women of child-bearing age. It appears that there is a tendency to diminish births at an earlier age in France than in other countries. In the number of births per 1,000 women in the lower age groups of the child-bearing period, France holds a fairly high place, but as the higher age groups of the period are reached the number drops considerably. This tendency is associated, not with an increase in childlessness, but with a decline

in the size of the family. The number of surviving children per family is now below 2.

Fertility. The crude birth-rate merely expresses the number of births per thousand of the total population irrespective of age and sex. Neither this rate nor the balance between it and the death-rate is a true measure of the capacity of a population for further increase. A population may be preparing for decline while it is actually increasing in numbers, for the capacity of a population for further increase depends upon its fertility and its mortality in different age groups below 50. The fertility of a population clearly depends upon the number of women between 15 and 50—the reproductive period. But since the younger women have a higher fertility than older women, the composition of the population by age, especially the age of its women, is an important factor. The figures for *total fertility* show how many children would be born on an average to 1,000 women passing through the child-bearing age (i.e. between the ages of 15 and 50), assuming that current rates of fertility at all ages remain unchanged, and that none of the women in question die during that period. The figures are obtained by adding together the numbers of children born to every thousand women during each year of age.

Total Fertility

France:	1935	2,045		England and Wales*	1931	1,920
	1936	2,045		Netherlands:	1936	2,591
Germany:	1934	2,032			1937	2,543
	1936*	2,212				

* Data uncertain.

From *Statistical Year-book of the League of Nations, 1938-g*, pp. 60-1 (Geneva, 1939).

The figure for France means that, according to the fertility rates in 1936, a thousand French women would give birth to 2,045 children during their reproductive years, assuming that none of the women die before they reach 50. But since the number includes both boys and girls it is not a measure of the extent to which the population is equipping itself for reproduction. This is expressed by the number of girls born to every woman during the child-bearing years, since these will be the potential mothers of the future. In France this figure, which is called the gross reproduction rate, averaged 1'004 for the years 1935-6. This is to say, at the current rate of reproduction the number of women will just be maintained, provided that all these girls live through their childhood and reproductive years.

Net Reproduction Rate. But some of the girls will die before they reach the child-bearing age and some will not live through the reproductive period. The effective reproduction is thus represented by a figure which allows for such losses by death among females between birth and the age of 50 years. This figure is known as the *net reproduction rate*. When this correction is made, it is found that in France, according to the fertility and mortality rates of 1936, every thousand women will be replaced, not by 1,004 girls, but by 880 girls. That is to say, a thousand mothers were replaced by only 880 potential mothers; this represents a net reproduction rate of 0·880. The net reproduction rate is thus an indication of the extent to which a generation is likely to reproduce itself according to current rates of fertility and mortality. It shows the probable ratio between female births in two successive generations, and indicates whether the population is likely to increase or decrease. A net reproduction rate of 1·0, if maintained, means that the population is likely to remain constant provided that fertility and mortality do not change.

In France the net reproduction rate has remained below 1·0 for the greater part of this century:

Net Reproduction Rates

1908-13	0930	I	1935	0866
1920-23	0977		1936	088
1925-27	0929		1937	0·87
1928-33	0905			

From *Statistical Year-book of the League of Nations*, 1938-9, P- 62 (Geneva, 1939).

At the present rate, therefore, the population of France is not reproducing itself. In this it is not alone in Europe, and in several countries a similar position exists; in some, even the net reproduction rate is lower, and therefore the rate of decline is likely to be greater than in France.

Future Trends

It appears that if fertility and mortality remain unchanged, the population of France in 1985 may be expected to amount to only 34 millions. If fertility and mortality diminish at the rate of diminution now prevailing, the population would be only 29 millions. It must be remembered that in recent years the increase in the population of France has been due to the greater relative number of children born to foreigners resident in the country. A continuation of the present position would mean that, apart from any changes in the numbers of foreigners in France, the younger generation would include an appreciably increasing proportion of children of foreign parents (see Appendix I). The death-rate is higher than might be expected, and to this extent is perhaps capable of reduction. On the side of the birth-rate the position is largely an inheritance of the fact that France is the most advanced of European countries in the history of population limitation during the past century. This is not the place to speculate upon the causes of this trend; the special factors frequently cited as being relevant to the position of France are the desire of the peasant in a country where equal division of inheritances is the rule to limit the number of heirs to a landholding, and a fear of the future owing to the rise of a powerful Germany. The occurrence of this trend in many other European countries suggests that these special factors have not really influenced the position very much. The crux of the matter is the unique combination or intersection of historical and geographical situations—that the country about to show a decline in the rate of population growth before other countries should lie adjacent to a new united Germany, which had a population equal to that of France in 1860, and in which the retardation of growth was not to appear for a number of years.

REGIONAL VARIATIONS IN THE GROWTH OF POPULATION

Introduction

A short survey over the last 80 years will indicate the nature of the problems which arise from the unequal rates of increase or decline in France as a whole. During the first half of the nineteenth century all parts of France experienced an increase of population, although already, by 1851, three departments in Normandy and three in Aquitaine had begun to show a slight decrease. The years around 1851 are generally taken as the dividing line in the history of French

population, for it was then that the development of coalfields, extension of the railways and the growth of the cities began to exert a decisive attraction upon the countryside.

From 1851 to 1881 thirty-seven departments showed a decline: not only in Normandy and Aquitaine, but in the Alps and the interior of eastern France—the Meuse, Champagne, and Burgundy. Between 1881 and 1911 these tendencies to decline were accentuated by the agricultural depression that began in the 'eighties. The areas of declining population now included sixty-three departments. Brittany and the Vendee began to show a decline, but in Normandy and Aquitaine the rate of decrease slowed up a little, although this was due largely to immigration; the departments of the Central Massif and Alpine regions continued to decline. The period 1911-26 was exceptional owing to the war of 1914-18, but even so there was no violent distortion of tendencies already at work.

By 1926 the main readjustment of disturbances brought about by the war of 1914-18 had probably been completed. Between 1926 and 1931 the total population of the country grew from 40,744,000 to 41,835,000, or by 1,091,000. Forty-six departments showed an increase, and forty-four a decline. The increases were chiefly in the following areas:

- (1) the Paris region, where the department of Seine-et-Oise showed the enormous expansion of 48 %;
- (2) the industrial north, especially Pas-de-Calais;
- (3) the departments bordering the north-east frontier;
- (4) the coast of Provence, where a considerable increase took place;
- (5) around Lyons, with a moderate increase;
- (6) Languedoc;
- (7) the Garonne valley, though the increase was very small.

A decline occurred over most of the Central Massif and the west, as well as in the inner Alpine departments and the upper Saone and upper Marne regions.

In the period 1931-6 the total population increased to 41,907,000, by the very small amount of 72,000: the actual increase of the French people had been considerable, 508,000, but was set off against a decline in the number of foreigners of 436,000. The number of departments increasing was now only thirty-six, and the number showing a decrease had risen by ten to fifty-four. The regions of increasing population were similar, although several changes **had occurred**. The **rate of growth around Paris** was slowing down; **that around Marseilles** was

continuing. The decrease in some areas must be ascribed to economic depression; thus Pas-de-Calais now showed the maximum decrease of any department, and Meurthe-et-Moselle and Loire also declined contrary to their previous increases.

Fig. 11. Population changes, 1911-31

Based on the *Atlas de France*, Plate 77 (Paris, 1933).

To sum up: The growth of population in France since the Industrial Revolution resembled that over much of Europe—an increase in urban areas, a decrease in the countryside. But in France the rate of growth was less than in Germany, while the exodus from the countryside was particularly great. These two factors were causing increasing concern to all thinking Frenchmen,

GROWTH AND DISTRIBUTION OF POPULATION

Analysis of the Movements of Population

Three factors bring about inequalities in the growth of population within the country. They are variations in the balance of births and

Fig. 12. The balance of births and deaths: excess or deficiency of births over deaths per 1,000 of the population, mean annual rate for the period 1922-31

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le debut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 375 (Paris, 1935).

deaths, internal migration between different localities, and immigration from foreign countries.

Births and Deaths: Geographical Distribution. Throughout France

the local variations of the ratio between births and deaths show two principal features. The first, an excess of deaths in many of the larger cities, is not uncommon. The second is more peculiar to France; it is the unevenness of the ratio over rural areas. The main features shown in Fig. 12 relating to the years 1922-31 have been equally true for most of the period since 1851. Broadly speaking, in the northern half of the country, births exceed deaths, and in the southern half deaths exceed births, except in three small areas—the departments in the Vendee, in the southern part of the Central Massif, and in Basse Pyrenees (the Basque country). The most extreme deficiency is found in the Aquitaine Basin and in the departments of the Yonne, Nièvre and Allier. Here, the ratio between births and deaths is so adverse that, if it continued, the population would disappear within 200 years, and the maintenance of population therefore results from immigration.

Internal Migration. The movement of population between different districts within France has become greater since the middle of the last century. This mobility is true of many countries, but it seems to be particularly true of France. In 1851 the percentage of the population living in departments other than their native ones was 10; in 1926 it was 32. As might be expected, this percentage is much higher in cities. For the last 50 years two-thirds of the inhabitants of Paris have been born elsewhere; there are said to be 80,000 Parisians of Savoy origin and 400,000 from the Central Massif, and in recent years the same proportion is true of the department of Seine-et-Oise. Again, during the period 1861-1926 the percentage of non-native inhabitants increased in the Rhone (Lyons) from 28 to 50, in the Bouches-du-Rhone (Marseilles) from 23 to 50, and in the Gironde (Bordeaux) from 15 to 32. A similar development took place in districts of expanding industry and hydro-electric power; in 1926, of the 87,000 inhabitants of the city and adjoining urban areas of Grenoble, 25,700 originated in Grenoble, 26,500 in the surrounding department, 37,500 in adjoining departments, 11,000 in distant ones, and 12,000 were foreigners. Fairly high percentages are found in l'Herault (38) (in the wine-growing district of Languedoc), and in the depopulated agricultural districts, reaching 25-33 in Lot-et-Garonne and Tarn-et-Garonne. The highest percentages of non-natives in the whole of France are to be found along the coast of Provence; Var has 50 and Alpes-Maritimes 64 (33 French and 31 foreigners). Departments with the lowest percentages of strangers are in the west of France and over the Central Massif.

The population changes since 1919 are summarized in Fig. 14, which shows two distinct areas in France. In the north-west and centre there is a steady decline in population, a small proportion of foreigners, a high proportion of stay-at-home elements, and very few

Fig. 13. The distribution of people living outside their native department, 1926
Based on the *Atlas de France*, Plate 78 (Paris, 1933).

towns of any size. In the north, east, and south, on the other hand, there are greater fluctuations—there is often an increase, but sometimes a decline; here live the great majority of the foreigners; hither come all the migrants from the north-west and centre, as well as migrants from shorter distances within the zone itself. This zone contains most of the medium-sized towns and all the large cities save two.

Fig. 14. A summary of population movements, 1919-34

Based on G. Mauco, 'Remarques sur le Mouvement de la Population en France depuis le ddbut du XIX^{me} siecle', *Annales de Geographie*, XLIV, 379 (Paris, 1935).

The shaded area represents the departments of central and north-western France, in which, as a whole, population has declined; few strangers and foreign immigrants are found there, and emigration to other parts of France is considerable; there are few cities of any size. Compare with Figs. 11, 12, 13, 25, 104.

Rural Depopulation

The decline of population in the countryside is a matter of very serious concern to many thoughtful people in France. Two facts must be borne in mind, however. In the first place the phenomenon is part of a widespread movement in Europe and North America. In the second place the decline is found not only in inhospitable areas like the mountain regions of Europe, but also in many well-favoured regions. In England, for example, both Herefordshire and west Suffolk showed a slight decrease in 1911-31. France is not the only country which experiences a drift to the towns.

Figs. 15 and 16 indicate that much of the territory which has experienced decline consists of the mountain departments of the Alps, Pyrenees and Central Massif. Here a hard struggle has been given up in favour of life in more favoured parts of the same region, or in other countrysides, or in towns. In some valleys a declining density

Figs. 15 and 16. The decline of population, 1846-1936. Each dot represents a loss of 2,000 inhabitants in the period shown. Based on E. Levasseur, *La Population Francaise*, 1, 401-20 (Paris, 1889) and successive *Annuairees Statistiques* (Paris).

of population higher up has been partly offset by an increasing density lower down, though often enough, in the Alps, this is due to foreign immigrants. The general result has been that the thirty-one mountain departments of France have shown a declining population most of the time since 1850, some losing up to 30% between 1851 and 1931. In places the results are impressive to the outsider: the purely rural valley of the Ubaye in the Alps declined from 17,000 to 12,000, whole hamlets being abandoned; some of the higher villages now possess only a quarter of their earlier population. The influence of industry in the mountain regions has been unequal. Diversified small-scale industries have had the effect of retarding the decline in some districts. In the Jura, for example, the two non-industrial arrondissements of Lons-le-Saunier and Poligny declined by 24% from 1836 to 1901, while the more industrial arrondissement of Saint-Claude declined by only 4%. Hydro-electric development has helped to maintain such industries, but where it has led to large-scale specialized industry there has been frequently a need to import foreigners. In the Maurienne, Tarentaise and TOisans valleys of the Alps, industrial plants largely recruited their labour from Italians and others.

These mountain regions reached their peak of population in the middle of the nineteenth century. Savoy, for example, had a maximum of 564,000 in 1838, while its population in 1931 was about equal to that of 1800. A state of over-population existed; the peasants were forced to cultivate ungrateful soil that would not yield an adequate return; housing and hygienic conditions were bad; crops were uncertain; and the people suffered from under-nourishment, stunted growth, and deficiency diseases. Indeed, in many mountain departments it is possible to regard the increase in the first half of the century, rather than the decline in the second half, as the abnormal and undesirable feature. With improved communications, emigration grew.

The Central Massif has seen various degrees of decline in population. The figures relating to its departments sometimes conceal the situation in rural districts owing to the growth of small towns. In the south-west, the department of Lot has been declining especially after 1881, but this is not surprising in the poor and limited environment of the Causses. On the north-western edge, Creuse is in a similar position. The two most mountainous departments, Haute-Loire and Lozere, in the south-east, declined greatly between 1911 and 1931. On the northern border Allier demonstrated some striking examples, for here the environment is not so adverse; the result has been a

decrease in the number of large communes and an increase in the number of small ones; twenty or more are in sight of disappearance; across the *campagnes* of the Bourbonnais more than 1,700 houses stand empty or ruined. In the Central Massif as a whole, however, the decline has largely involved the abandonment of land on the margin of economic cultivation.

A comparison of Figs. 15 and 16 with the preceding maps shows that the problem of rural depopulation is much more than that of mountain peasants leaving a difficult environment. The four main areas of most persistent decline have been Normandy, the Seine-Saone region, the centre and south-west, and the Alps, while in each of these lie departments which have experienced, at certain periods, the maximum rate of decline. Two of these, Normandy and the Seine-Saone region, have no mountain departments, while the central and south-western area includes most of the Aquitaine Basin and Charente. In the Orne the decrease is not surprising, for it is an area of poor soil; but in the Aube, Haute-Marne and Meuse, the background is not repellent, if not very attractive. In Aquitaine the departments of Lot-et-Garonne, Gers and Tarn-et-Garonne contain countrysides long regarded as among the most fruitful in Europe. The last factor to be remembered is that the two northern areas lie in that part of France where births normally exceed deaths, but that those of the Aquitaine basin are in the south where deaths normally exceed births. Migration is selective. It is usually the younger people who leave home, with effects upon the number of marriages and the birth-rate, while since the remaining population includes a greater proportion of old people, the mortality is higher. The average death-rate for France is 15 per thousand, but in the Lot department it is 20. Every year this department loses 52 people out of every 10,000 through the excess of deaths over births. It is not surprising therefore that the number of foreigners engaged in agriculture in Aquitaine is a high one. (See Appendix I, Foreign Population in France.)

In some districts of the south-western area lie 'fields untitled, plum trees in blossom and the buds ready to burst on the vine trellises of deserted houses'; another writer talks of a dying countryside. In one recent period there were 2,500 vacant farms in the department of Gers; in some districts the price of land is little more than a quarter of what it was in 1872. Perhaps in the short view of one or two generations the problem appears more serious than it really is, for the history of a countryside is a long-term matter. In the past, in **Europe, there** have been many examples of foreign colonists repopu-

lating deserted localities. But it is undeniably a matter of serious concern, for there seems to be an increasing prospect that in parts of France 'more and more foreigners will come to live easily on a soil which generations before made rich and prosperous*.

No doubt many factors have been at work. As in other countries, the expansion of modern industry has discouraged the rural craftsman; improved methods in agriculture have sometimes reduced the need for labour; some peasants have left land which provided only a moderate return for the expanding market-garden industry. As elsewhere, it seems that the younger people have preferred the shorter hours and regular wages of the towns. It is possible, too, that the peasant feels that he receives less social regard than the townsman, although fortunately there appears to be a reaction against this attitude. The view most commonly advanced is that one factor in the problem is peculiar to France. It is that in areas where subdivision of holdings has gone very far the small peasant is disinclined to produce a further break up of the land and so limits his family. The factor is held to apply particularly in the south-west, and an investigation of conditions in the Chalosse district of the Landes department seems to bear out this view, for population has declined most in the east of the district, towards Gers, where there are more peasant properties; in the western area, where there is more *metayage*, the peasant is much less frequently a proprietor and has not therefore feared division of the land.

Progress has been made in some rationalization of rural population: in 1920, several departments in the Aquitaine Basin began co-operating with the coastal departments of Brittany to settle cultivators on vacant holdings in the south-west. Belgians, Swiss, and Poles were also brought in. The warm climate, however, appears to have adverse effects and the immigrants suffer easily from fatigue. The Comite regional du Sud-Ouest subsequently turned to Spaniards and French Canadians.

RURAL SETTLEMENT

Main Types of Settlement

The study of rural settlements has made considerable progress in France in recent years, and it is now possible to make fairly satisfactory generalizations about the distribution of villages, hamlets and isolated farms. To take one example: western Normandy and Champagne show two widely different arrangements of habitation. In the

former, in the department of Manche, there are 18,930 inhabited places, while in a district of the latter a population but 14% smaller is found in only 1,580 inhabited places. Clearly, in western Normandy the population is very dispersed, either in small settlements or in single farms, while in Champagne it is grouped into villages.

Fig. 17. Types of rural settlement in France

Based on the *Atlas de France*, Plate 80 (Paris, 1938).

Where settlement is 'nucleated' most dwellings are grouped in villages.

Fig. 17 presents a generalized picture of the types of rural settlement in the whole of France. The most striking feature is that the north and east is predominantly a land of villages. They are not, of course, confined to this area; they become more frequent again, as the Mediterranean is approached, and in Langiiedoc many villages are prominent on heights that could be easily defended against the

pirates of earlier days. Other restricted areas of villages are the regions around Caen in Normandy, of the Planeze in Auvergne, and about the middle Adour in the south-west. The Alps and Pyrenees are not without true villages, but here conditions are naturally more variable. On the other hand, there are localities in the north-east where the true village is rare. Many hamlets can be found in the Pays de Caux, in Brie, and on the western slopes of the Vosges, while in eastern

Fig. 18. Scattered farms and hamlets in Brittany (near Rennes, department of Ille-et-Vilaine)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 75 NE, Rennes, reproduced from the French 1 : 80,000 (1901).

Flanders many single farms have been established in recent centuries away from the original settlements. These exceptions, however, do not invalidate a generalization about the north-eastern distribution of the true village in France.

Relatively dispersed or scattered settlement, on the other hand, covers about two-thirds of France—in the west, centre, and south, except near to the Mediterranean. In 1787-9 the English traveller, Arthur Young, noticed, for example, in the Basin of Aquitaine, how farms and houses were scattered everywhere. The most pronounced

dispersal is in Brittany, in western Normandy and over most of the Central Massif; in many localities of these regions more than two-thirds of the population lives in dispersed settlements. The French geographer De Martonne describes the countryside of Brittany as follows:

'No more villages of houses clustering together like those of the Paris Basin. Near the church steeple you will see only two or three houses, the school and the mairie, one or two inns, a forge if you are

Fig. 19. Villages in north-eastern France (south-west of Amiens, department of Somme)

Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE Neuchatel, reproduced from the French 1 : 80,000 (1901).

on a main road. Each peasant makes his living in the middle of a little domain which he works in his own way. Around the farm he has his pasture and his fields, all enclosed by hedges of trees growing in banks of earth/

Dispersal of settlement is not quite so absolute in Brittany as this account would suggest, for while it is true that the village of eastern France is absent, there are embryo villages or superior hamlets which occur all the way towards Normandy. Often, these subsidiary settlements possess their own small chapels dedicated to local saints.

Geographical and Historical Factors in Settlement

The readiest explanation of these contrasts in settlements is that they reflect differences in water supply. Thus, impervious rocks and many springs seem to favour dispersal of dwellings, while a limestone area, where water is restricted, seems to demand a grouping of habitations around a spring or well. This factor must have influenced the choice of sites in the early settlement of France, but it was not the chief factor and there are many anomalies. In parts of the middle Garonne valley, for example, people have preferred to live on the low plateau tops and to fetch their water from a distance. In Languedoc there are villages located near a few hectares of good land in preference to being near a spring, and many good springs are without a village. In the Pays de Caux, where the subsoil is chalk and water is limited, the population is dispersed in the west and nucleated in the east. The nucleated villages of eastern France are found alike on the well-watered Ardennais plateau, on water-bearing clays and on permeable limestones. Throughout wide areas over both the clays of humid Champagne and the chalk of dry Champagne, over 85 % of the population is in grouped settlements. Villages are also widespread around Langres, where a considerable variety of soils occurs in a small area. The neighbourhood of Langres itself consists of a plateau of Oolitic limestone considerably dissected by the westward-flowing headwaters of the Marne, so that a heavy marl is exposed in the valleys; eastwards lie alternate tracts of limestone and clay or marl which differ considerably in soil, and in water supply. Over all this area settlement seems to have taken no account of differences of soil and water supply, for villages are found on lower Lias sandstone, on the Jurassic plateau, on Oxford Clay, on the marls, and both where springs are frequent and where they are few.

These facts show that no simple and satisfactory explanation will cover all the differences in types of settlement to be found in France, and that they must be due as much to complex historical factors as to physical causes. The village was associated with a society dependent upon open field agriculture, and dating as far back, at any rate, as the fifth and sixth centuries, when France was settled by Franks, Burgundians and Visigoths (see vol. 11, p. 7) after the breakdown of Roman Gaul. The area of the true village in north-eastern France differs very little from the area of mediaeval 'open field' agriculture.

The base of this agriculture was two or three large open fields, divided into long strips and cultivated in common, together with

The geographical background of west and central France seems to have exercised a more obvious limiting effect upon the kind of economy possible to its inhabitants, and thereby to have restricted the possible forms of settlement to one of dispersal. The crystalline and metamorphic rocks of Brittany and the Central Massif provided abundant water and so permitted dispersal of settlement, but of more importance was the fact that these regions of older rocks, with wetter soils and more humid climate, offered less scope for agriculture to their inhabitants.

On these infertile lands more pasture was available. In some localities land was taken from the waste, cropped for a few years and then allowed to revert to its former condition; often only one or two harvests were secured at the price of fallows up to 20 or 30 years. This temporary cultivation remained a feature of Breton agriculture for a long period, being referred to as late as the eighteenth century. Finally, there have always been considerable areas of uncultivable land in these mountainous areas, and they remain to-day as *landes* or *montagnes*.

Historical Development

The map of settlement is, however, not merely a reflexion of the conditions which held when the Franks, Burgundians and Visigoths made their entry into France; it records also the modifications of later centuries. The most important of these was the clearing of woodland and the creation of new settlements, a process which began soon after the early settlement and continued intermittently until very recent times, for in the eighteenth century reclaiming activity secured exemption from some taxes. The greatest clearing seems to have taken place in the Middle Ages between 1000 and 1250. This progress was not evenly spread in space: in Poitou, unlike northern France, there is little record of colonization of wood and waste during this period. Clearings were apparently much older, and in the eleventh century villages were as numerous as they are to-day; indeed, many bore the names of Roman proprietors. Nor was the progress of colonization even in time, being broken at times by plagues, by warfare, or by the movement of population. During the fifteenth century the ravaging of cultivated land during the Hundred Years' War allowed an increase in woodland, in parts of western France, and in Saintonge the people for a long time said 'The forests came back into France through the English'. Similarly, after the Thirty Years' War, considerable extents of wooded country reappeared in the Jura.

The settlement that resulted from the colonization of woodland took various forms. It was based sometimes upon a nucleated village, as in the countryside around Langres; such settlements were usually old ones, following soon after the coming of the Franks and Burgundians. This is true of much of eastern France, where the forest

Fig. 21. A 'herring-bone' village in north-eastern France: the hamlet of Petit-Bois-St-Denis in 1715. (The hamlet to-day is in the commune of La Flamengric north of Vervins, Department of Aisne.)

Based on M. Bloch, *Les Caracteres Originaux de l'Histoire Rurale Frangahe*, Plate I, (Oslo, 1931)-

In a district which was originally forested individual clearings were often made piecemeal, each colonizer establishing his house at the end of a 'street', and acquiring a strip of cultivable ground running back towards the remaining woodland, at right angles to the road.

was less dense and natural clearings more frequent. Where clearings in woodland took the form of a progressive expansion from an existing settlement, however, the 'linear' village developed, for each successive settler built a house at the end of the road. Behind this house stretched his land in a single long strip running back towards the remaining woodland. This arrangement of spaced houses, with fields equal and

parallel and a single strip for each occupier instead of the intermixed strips of the open-field village, is sometimes called the 'herring-bone' type—in Germany the *Waldhufen*. In France much of this kind of settlement began in the thirteenth century: it is found particularly in the Ardennais region around Biesme, in the valleys of the Aisne and Oise, and above all in the Pays de Caux of Normandy, where the village of Neuville Champ d'Oissel is 4 km. long, and St Nicolas

Fig. 22. Modifications of original village settlements

(i) Fourcigny, in the extreme south of Picardy (west of Poix, Department of Somme). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 20 NE, Neuchatel, reproduced from the French 1 : 80,000 of 1910.] Near the centre of this commune is a hamlet, later in origin than the parent settlement but nearly as large. The hamlet originated as a clearing in woodland.

(ii) Allouville-Bellefosse, in the Pays de Caux, Normandy (west of Yvetot, Department of Seine-Inferieure). [Based on G.S.G.S. Series 4040 B 1 : 50,000, sheet 19 SE, Yvetot, reproduced from the French 1 : 80,000 of 1910.] Beyond the original village near the centre of the commune lie many later settlements, some of which represent early clearances in woodland, others, which only consist of a few farms, being later offshoots of these hamlets.

d'Aliermont is even 9 km. long. The third and most widespread type of settlement resulting from the colonization of woodland is fragmentary in character. It is found in most parts of France, but more particularly in Maine and Brittany. Place names often record this advance—the appellation *Les Essarts*, for example, means 'the clearing'. The *Foret d'Othe* has many names ending in *-grange*, *-essart*, *borde*, *-loge*, *-villeneuve* and *-neuville*; in the Perche region

many names end in *-iere* or *-erie*, prefixed by the name of the first colonizer; names ending in *-l'huys* in the Morvan, are similar, e.g. *l'huys Brechard* or *l'huys au Page*.

Much of this clearing, perhaps the largest amount, was carried on by individuals, but more is known about the organized colonization by ecclesiastical and lay lords. In eastern Normandy, for example, monasteries founded in the seventh and eighth centuries were usually along the Seine, often in territory long settled, but in the eleventh and twelfth centuries the new foundations were all inland in the heart of extensive forested regions. An interesting development took place in Maine, where the land is too broken and infertile to allow widespread agriculture, and where the large village and manorial system of the north-east had never existed. Here, the earliest settlement was an extensive scattering of single homesteads, but in the second half of the eleventh century small planned villages called *bourgs* were established by the Church, especially St Vincent of Le Mans. This example was followed by lay lords who built other *bourgs* in the west, *villes-neuves* around Paris, and *bastides* in Aquitaine. Analogous to clearing of woodland was reclamation of marsh. The draining of the polders along the north-east coast was started as early as the eleventh century. In the twelfth century in the Val d'Anjou and around Saumur the seigneurs extended their domains by beginning the construction of the Loire *levees*, and in the sixteenth century, under Sully, the swampy district of Bas-Medoc was reclaimed. Settlement varied in types, sometimes taking the form of isolated farms and sometimes of string-like villages along dykes and roads, as in the former marsh of St Omer in Flanders.

Later ages saw comparatively little change in the appearance of the countryside and none comparable with the enclosures of eighteenth-century England. In the north-east, farming improvements led to the creation of big farmsteads in Picardy and the lie de France. Arthur Young, in 1787-9 and 1794, was surprised to find that nine-tenths of the enclosed land of the west was worked in the same way as the open fields of the north-east, with similar rotations and with extensive fallowing. Just before the time of Arthur Young, however, there had begun a movement towards the destruction of the communal character of village agriculture. Three great investigations in 1766-87 examined the problem of *vaine pature* (the obligation upon each cultivator in an open field village to allow grazing over his stubble), and between 1767 and 1777 edicts allowed liberty of enclosure in much of the north-east, while elsewhere local edicts affected

single villages; but little came of these proposals. The French Revolution resulted in much land changing hands; the cultivator now had liberty to grow what he pleased, and the practise of common grazing on the stubble was attacked. As a result the custom of *vaine pature* gradually died out during the nineteenth century.

In short, the French countryside has not undergone very much change, except where it has been affected by industry. Whereas in England open fields were almost universally enclosed by the beginning

Fig. 23. Two types Of villages in the south of France

Based on the *Atlas de France*, Plate 82 (Paris, 1939).

(i) Ste Foy-la-Grande is an example of a 'bastide' village founded in the Middle Ages, and laid out on a rectangular plan. It lies on the Dordogne river, 30 km. east-south-east of Libourne, Department of Gironde.

(ii) Pierrefeu is an example of a Provencal village, with the older part lying on a hill as a defensive site near the Ste Croix Chapelle (shown by a cross). In recent centuries the village has extended downhill. It lies 25 km. north-east of Toulon, Department of Var.

of the nineteenth century, the *plaine* or *campagne* of north-eastern France has remained open, with relatively little alteration. The Midi, as always, has more land enclosed, often by stone walls. The lands of early enclosure, as in England, remain: hedges are frequent among the scattered farms *pi* the Aquitaine Basin, while to the west the Armorican Massif is still the *bocage* countryside with tree-lined hedges, although in places changes in economy and agriculture are allowing the hedges to decay.

TOWNS AND CITIES

Number and Distribution of Towns

Administrative divisions, which are the basis of census returns, frequently give a misleading picture of urban development, in that suburbs which are functionally part of a city are counted separately. It may be assumed that most towns and cities are in fact rather larger than they appear to be, in France as elsewhere.

According to the 1936 census there were in France 341 administrative towns with a population exceeding 10,000, apart from the suburbs of Paris in the Seine department:

Over 100,000 inhabitants	17
80,000-100,000 inhabitants	13
50,000-80,000 inhabitants	13
30,000-50,000 inhabitants	37
15,000-30,000 inhabitants	120
10,000-15,000 inhabitants	141

Over 10,000 inhabitants 341

A great many of the smaller of these towns are satellites of the great cities, and it is only through the maintenance of their administrative independence that they appear as towns in the census. The towns of the northern coalfield form a series of units which lie near each other and which are closely related in function.

Principal Groups of Satellite Towns

Population	Paris	Lyons	Bordeaux	Lille	St Etienne	Northern coalfield
80-100,000		1				
50- 80,000	2					
30- 50,000	1			1		3
15- 30,000	12	3	5	6	1	5
10- 15,000	27	2	2	3	4	15
	42	6	7	10	5	23

Other examples of suburbs which have maintained their administrative independence are Schiltigheim (Strasbourg), Sanvic and Harfleur (Havre), La Seyne (Toulon), Sotteville-les-Rouen, Petit-Quevilly and St Etienne-du-Rouvray (Rouen) and Montigny-les-Metz (Metz).

The larger cities of over 100,000 inhabitants were the following:

Paris (Seine department)	4,962,967	St Etienne	190,236
Marseilles	914,232	Havre	164,083
Lyons	570,622	Toulon	150,310
Bordeaux	258,348	Rouen	122,832
Nice	241,916	Nancy	121,301
Toulouse	213,220	Reims	116,687
Lille	200,575	Roubaix	107,105
Nantes	195,185	Clermont-Ferrand	101,128
Strasbourg	193,119		

There is clearly a small number of such cities in France compared with the fifty-five in Great Britain. Furthermore, there are only four in France with a population of over a quarter of a million, and only one city comparable in size with the British cities of Bristol, Leeds, Sheffield or Edinburgh. Of the seventeen cities in France with 100,000 inhabitants or more, seven are maritime ports and one primarily a river port, while six are primarily manufacturing and industrial centres, of which only three are at all similar to the English type of coalfield city. The differences result, generally speaking, from the different economic development of the two countries.

The smaller towns and cities of 50,000-100,000 inhabitants show equally the comparative absence of the specialized manufacturing centre in France. Of the twenty-six of this size, two are satellites of Paris—Versailles and Argenteuil, three are ports and one a naval base, four are primarily manufacturing centres like Mulhouse, Grenoble, Tourcoing and Villeurbanne, while of the remaining sixteen the majority are of a kind characteristic of France—the provincial city which is the business centre for a considerable area, and often the seat of a university or a bishopric. They are cities which have not grown so fast as the ports or manufacturing centres, yet have kept pace with progress. Such are Limoges, Amiens, Nimes, Montpellier, Rennes, Angers, Tours, Le Mans, Orleans, Avignon, Besançon. Some were capitals of provinces under the Ancien Regime, and are well fitted to-day to act as regional capitals.

The 157 towns of 15,000-50,000 inhabitants are more varied in their nature. Some are functionally part of larger cities: five, for example, are satellites of Paris—Meudon, Rueil-Malmaison, Livry-Gargan, Aulnay-sous-Bois, St Germain-en-Laye. There is still a number of 'historic' provincial towns, smaller than the regional capitals—Bourges, Poitiers, Angoulême, Périgueux, Narbonne, Nevers, Chartres, Albi, Blois. Several towns of this order of size are Riviera resorts like Cannes or Antibes; a number are ports,

such as La Rochelle; and many are substantial market centres like Haguenau in Alsace, Agen in Aquitaine, Bourg in the middle Saone valley. But a number belong to a type so common in England, though there they are often larger—the specialized town of the industrial age. Such are Le Creusot; Lens, Denain, Lievin, Henin-Lietard in the

Fig. 24. The distribution of urban population, 1931, as a percentage of the total population, by departments

Based on the *Atlas de France*, Plate 78 (Paris, 1933).

mining zone of the north; St Nazaire, the shipbuilding port; Cherbourg, the Atlantic pier-head; Dunkirk, the port for the northern coalfield; Colmar, a textile centre.

A prominent feature of French urban geography in the present century has been the Riviera resorts, some of which, especially Nice, the largest, are growing very rapidly. Paradoxically enough they draw

attention to a very curious feature of that geography, the complete absence of the seaside resort as it exists in England. This is not to say that the small watering place is not to be found on the French coast, but it is remarkable that there is no analogue to the large seaside towns of England, which are quite different from Nice and often attain a considerable size. In 1931, there were four English seaside resorts with a population exceeding 100,000 and five with a population of 50,000-100,000. The difference between the two countries is doubtless due in part to the greater urban populations to be found in England, though social characteristics are not without their influence. In fairness it should be pointed out that the curious feature about these parasite towns may not be their absence in France, but, as Professor Demangeon suggests, their existence in England.

The distribution over the whole of France of its larger towns proceeds fairly logically from the nature of the geographical and economic background. They are nearly all located on the coasts or near the frontiers of France. Of these peripheral cities, furthermore, the majority lie near the eastern or continental frontiers—only Nantes and Bordeaux are situated on the Atlantic coast. Clermont-Ferrand, the only centrally located French city, was the latest to attain a population of 100,000. The distribution of all the towns and cities over 10,000 is, of course, more widespread, in that many of the smaller ones derive much of their function from serving the surrounding agricultural population. Several concentrations stand out—the Paris region, the northern coalfield, the Meurthe-Moselle valley, the plain of Alsace, the Riviera coast, and Languedoc. The southern region of the Alps, the Landes, the Pyrenees and the highest part of the Central Massif stand out as gaps. Over the greater part of the Massif, however, in spite of the considerable extent of thinly populated territory, urban centres are as well developed as in Brittany.

There are very few towns and cities south-east and south-west of Paris, a situation which is mainly a repetition of the general map of population distribution, and in this large area the sparsity of towns is striking. Beyond the satellites of Paris itself, within a radius of 100 km. (60 miles) of Paris, there is only one town with a population exceeding 20,000 (Chartres). Thirty years ago Brunhes drew attention to the fact that within this circle there was no city of 50,000, but the absence of small towns is even more remarkable. The situation is very different in the neighbourhood of London: not merely are there the coast towns, and the swarm of small towns in Kent, Surrey, Middlesex and Essex, but also, to the west and north-west, a number of centres

which have expanded very rapidly in the period 1911-31—Bedford, Luton, Aylesbury, Uxbridge, Watford, Slough and Reading, of which

Fig. 25. Cities and towns with over 15,000 inhabitants, 1936

Based on *Annuaire Statistique*, 1938, Table 2, pp. 5-8 (Paris, 1939).

The number of towns and cities shown is 200; this number does not include the fifty-three administrative towns which are suburbs of Paris within the Seine department, although the 'satellites', such as Versailles and Argenteuil, appear. The two separate administrative towns of Roubaix and Tourcoing are shown as one town. The towns in southern England are shown for purposes of comparison, according to the 1931 census of England and Wales. A, Amiens; An, Angers; Av, Avignon; B, Bordeaux; Bn, Boulogne; Br, Brest; Bs, Besancon; Bz, Beziers; C, Caen; Ch, Cherbourg; Cs, Calais; C-F, Clermont-Ferrand; D, Dijon; Dr, Dunkirk; G, Grenoble; H, Havre; L, Lille; LeM, Le Mans; Lm, Limoges; Ls, Lyons; M, Marseilles; Mn, Montpellier; Ms, Mulhouse; Mz, Metz; N, Nantes; Ne, Nancy; Ni, Nice; Nm, Nimes; O, Orleans; P, Paris; Pn, Perpignan; R, Rouen; Rm, Reims; Rn, Rennes; R-T, Roubaix-Tourcoing; S, Strasbourg; StE, St Etienne; StN, St Nazaire; T, Toulouse; Tn, Toulon; Tr, Tours; Ts, Troyes; V, Villeurbanne.

the last named had almost reached 100,000 in 1931. Figures of total populations in the neighbourhood of the two capitals demonstrate this difference clearly enough: within 30 km. of the centre of Paris

(18 miles) there were 6,000,000 and beyond this up to 100 km. the population increases only very slightly above that figure. In the London region, on the other hand, within a radius of 100 km. there is a population of between 11 and 12 millions. It is clear that the metropolitan regions of the two countries are fundamentally different.

Fig. 26. The growth of French cities in the nineteenth century

It can be seen that all the French cities grew slowly in the early part of the century, but from 1840 to 1850, when the influence of railway building made itself felt, the majority began to grow much more rapidly.

Urban Growth.

The growth of French cities has generally proceeded differently from that of English cities. In the 40 years after 1800 no French town showed any great increase comparable with the increases which were taking place in the English coalfields at that time. From 1800 to 1840 only Lyons, Marseilles, St Etienne and Lille grew to any extent. It was through the development of railways that the expansion of most French towns was accelerated, for there was a general increase in the rate after 1840. The increase was not uniform however: Rouen continued to grow very slowly for the rest of the century; Nantes, Toulouse, Toulon, and Reims experienced a moderate increase; the rapidly growing towns now included Bordeaux, Havre and Nancy as well as Lyons, Marseilles, St Etienne and Lille. It was not until

1895 that the population of Marseilles exceeded that of Lyons. Soon after its acquisition by France, Nice began a rapid expansion which has since continued. Clermont-Ferrand is the only large city which can be called a product of the twentieth century.

Recent statistics are sometimes reduced in value by the tendency to-day for population to shift to the outer rim, but they give some idea of expansion if not decline. The most rapidly growing of the smaller cities are the following:

Population in 000's

	1926	1931	1936		1926	1931	1936
Rennes	83	88	98	Le Mans	72	77	84
Dijon	83	91	96	Metz	69	79	83
Grenoble	85	90	95	Brest	67	70	79

Limoges, Amiens, Nimes and Montpellier, all of which have over 90,000 inhabitants, are growing more slowly; Mulhouse declined from 99,000 to 96,000, though the whole agglomeration of city and suburbs continues to expand.

Population of the sixteen largest cities after Paris {in 000's}

	1926	1931	1936		1926	1931	1936
Marseilles	652	801	914	Strasbourg	174	181	193
Lyons	571	579	570	Havre	158	165	164
Bordeaux	256	263	258	Rouen	123	123	123
Lille	202	201	200	Roubaix	117	117	107
St Etienne	194	191	190	Toulon	115	133	150
Nantes	184	187	195	Nancy	114	120	121
Nice	184	219	242	Clermont-Ferrand	111	103	101
Toulouse	181	194	213	Reims	101	112	117

Among the largest cities the most obvious feature is the continued growth of Marseilles at such a rapid rate, for 262,000 or 40 % in 10 years is more characteristic of American cities; it is more rapid than the rate during its expansion towards the end of the nineteenth century, and in France has been exceeded only a few times during the expansion based upon railways and industry 60 or 70 years ago. The next most rapidly growing town is Nice, with an increase of 31 % in the 10 years 1926-36, and next are Toulon 30 %, Toulouse 17 %, and Strasbourg 10 %; Nantes (6 %) showed a modest increase.

It would not be correct to assume that the remaining cities have declined or remained stationary as they appear to have done, owing to the movement of population to the surrounding communes in many

instances. Thus Rouen appears to have remained with a population **of 120,000** ever since 1900, but in reality the left-bank suburbs and tributary towns have expanded considerably, until in 1936 the entire agglomeration totalled 260,000. The percentage of the population living on the left bank grew in 36 years from 25 to 43, and the number is now 111,000. Similarly, Dunkirk had only 31,000 inhabitants in both 1931 and 1936, whereas in the latter year it can be claimed that the population of Greater Dunkirk was 95,000. It is clear that an account of 'conurbations' or city and town groups, rather than of census divisions, would give a true picture of city growth in France, although it should be mentioned that the examples of Rouen and Dunkirk are rather exceptional, and that the discrepancies between the statistics for administrative cities and conurbations are not all so considerable. (A 'conurbation' is a group of towns and cities of which the built-up areas are contiguous.)

Conurbations

A French investigator, J. Soulas, has compiled a statement of conurbations and their populations for the census year 1936, and his findings are appended below. According to this list there were in that year twenty-nine conurbations in France of more than 100,000 inhabitants, with a total population of 12,500,000, or almost one-third of the population of the country. It will be noticed that only one is a 'million' conurbation. Working on a similar method, Professor Fawcett calculated that Great Britain possessed thirty-seven in 1931, of which, however, seven exceeded a million, while the total conurbation population was 26,800,000, or nearly 60 % of the national total. While in Great Britain a number of the administrative cities 'disappear' in the list of conurbations (there were 54 cities of 100,000 or more and only 37 larger units), in France only one of the 100,000 cities 'disappears' owing to the combination of Lille and Roubaix, and thirteen larger groups are created from the administrative cities of under 100,000 by the inclusion of their adjoining communes. English students will probably find that the French list implies far too generous a standard in the delimitation of several of the conurbations, and that on a precisely similar basis several of the mining valleys of south Wales could be classed with the larger units. Aix, for example, lies 20 km. from the nearest part of Marseilles. Nevertheless, the list is of value in drawing attention to the chief centres of urban population in France.

***Population in 1936 of the twenty-nine French Conurbations of
'more than 100,000 Inhabitants, after Soulas***

Conurbation	Population in 000's	No. of com- munes included	Principal communes
1. Paris	5,500		
2. Marseilles	990	9	Marseilles 914; Aix 43; Aubagne 14
3. Lyons	802	32	Lyons 571; Villeurbanne 81

28. Dijon and suburbs	105		Dijon 96
29. C6te d'Azur from Cannes to Antibes	102	7	Cannes 49; Antibes 25; Vallauris 10

NOTE ON FAMILY ALLOWANCES

Since the middle of the nineteenth century the slowing up in the rate of natural increase of the population has attracted considerable attention, and in a variety of ways attempts were made to encourage larger families. An extensive literature appeared over a number of years. Private and semi-private organizations, such as the *Alliance Nationale pour l'Accroissement de la Population*, were formed to carry on propaganda, while twenty-one private endowments, such as the *Fondation Cognac-Jay*, have been established to grant subsidies and prizes to large families, several hundred thousand francs being distributed annually. The government introduced, from the end of the century, measures providing tax exemptions, invalid, relief, poor relief, exemptions from military burdens, reduced rates for rail travel and other concessions for parents. These measures were carried further after the war of 1914-18. The government also set out to define its attitude to birth control and abortion. A law of 1920 makes propaganda in favour of birth control and abortion an offence. A law of 1923 changed the legislation concerning abortion, making the act of abortion a misdemeanour liable to moderate penalties, a measure thought likely to be more effective than the previous legislation which regarded it as a serious crime. Neither of these two laws is considered to have much effect, and some authorities consider that in France the annual number of abortions exceeds the annual number of births.

The most important of the measures for the encouragement of larger families is the family allowance system, which has now become widespread. It is based upon the assumption that if parents are given financial assistance towards the cost of rearing children they will be encouraged to have larger families. The earliest allowances in France, however, were begun many years ago by employers for quite different reasons, mainly as a measure of securing a stable labour supply. It is only in the last two decades that family allowances have come to be regarded as a positive means of influencing the population position.

As early as 1854 a factory owner had established a fund to give assistance to his employees who had families to support, and later some government employees were also given financial assistance. During the war of 1914-18 the system spread, beginning with engineering firms in the Grenoble region, and by 1920 there were 230 employers operating family allowance funds for 50,000 employees, distributing annually 4 million francs, while all lower paid categories of public servants were also receiving allowances. The state example

of paying family allowances encouraged the extension of the system to industry, and the shortage of labour in the years 1918-30 provided further incentive to employers to pay these allowances, in order to secure greater stability of labour by the employment of the largest possible number of married men with children. Another motive for the employers was a belief that allowances helped to withdraw family men from interest in the class struggle. To employees the scheme appeared as a means of raising their standard of living. In 1932, some 245 funds covering 1,850,000 employees, and distributing annually 380 million francs, were in operation, and affiliated to a central organization. As the number of private funds grew in these years, the rate of allowances paid to state, departmental and municipal employees increased. Eventually, in 1932, legislation was effected by which all employers were ultimately to subscribe to 'equalization' funds and to grant allowances for dependent children to all French and foreign wage earners and salaried employees.

In 1933 the number of beneficiaries amounted to 5 millions. The programme was extended to more industries, and in 1936 the system was made applicable to all industries and commercial undertakings employing more than ten people, including multiple branch concerns, while in the same year the law was extended to agriculture. The wide extension of the scheme is shown by the fact that the total payments in 1937 were 1,340 million francs, compared with 872 millions in 1936, and were estimated to reach 1,500 million francs for 1938.

Considerable variations were naturally to be found between different areas, both in the rates paid and the subscriptions levied on employers, owing to local differences in wage levels, cost of living, etc. The table on p. 79 illustrates certain rates.

When the scales were revised in 1938, it was provided that the minimum rates should be fixed by the Minister for Labour on the recommendations of the Higher Family Allowances Commission. The age to which allowances were payable for children, apprenticed or pursuing a course of studies, was raised to 17, but after November 1940, no allowance was to be payable for an only child over 5 years old. The new arrangement came into force in April 1939. ,

Machinery for Payment. Funds for the payment of family allowances are obtained entirely by subscriptions from employers. The charges amount to over 2% of the total wages bill in industry. Beginning in 1918, Equalisation Funds (*Caisses de Compensation*) came to be established as a means of regularizing the financial side. Employers contribute to the appropriate funds according to the

number of people they employ, and each fund then distributes the allowances. The Act of 1932 did not create any special machinery for the administration of family allowances, and the existing funds set up by employers were left untouched. Employers not already affiliated to equalization funds were obliged to subscribe. It is important to notice that in order to prevent employers from reducing their liabilities by employing unmarried staff, subscriptions to the funds (*caisses*) are payable for all workers, whether married or single. In 1938 a national compensation fund was established to make grants to local compensation funds, on which the charges were found to be abnormally high. The national fund, which is to be managed by the *Caisse des Depots et Consignations*, is to obtain its resources from subscriptions paid by all the local compensation funds. Until 1932 the subscriptions paid by employers were all voluntary.

Rates of Family Allowances, francs per month

	One child	Two children	Three children	Four children	Each ad- ditional child
1936: normal rate	30	70	120	200	80
1936: rate for state employees	52	76	157	196	—
1937: rate in Paris	30	80	200	400	200
1938: rate in Paris	60	160	300	500	200
1938: rates in agriculture	15 to 25	30 to 85	67'5 to 200	110 to 320	27'5 to 120
<i>Rates as percentages:</i>					
1938: rate in Paris as per- centage (approx.) of mean wage of 20 skilled trades	4	10	18	30	12
1939: minimum rate at re- vised scales for the whole of France, as percentage of adult male wage earner	5	15	30	45	15

Conclusion. It is probably too early to form a judgement upon the effectiveness of family allowances in retarding the decline of the birth-rate. The widespread application of the system has been in effect for too short a time to permit of statistically sound conclusions being drawn. As to the funds which were privately operated by firms on a considerable scale soon after 1920, such as the Michelin Company's fund for its employees at Clermont-Ferrand, it is held by some authorities that the higher birth-rate occurring among the beneficiaries of the funds represents inconclusive evidence. The employees are not a typical cross-section of the adult population as

a whole, and some of the employees may have migrated to the Michelin works so as to take advantage of the allowances.

While the payments under the schemes add to the income of parents, the addition is considerably less in amount than the increase in the cost of living incurred through-children. It has been estimated that three children add to the income of a lower grade civil servant an amount equal to only half of what they add to his cost of living. Hence it is considered by some that the scale of family allowances is too small to have any real effect upon the population position. At the most they may have resulted in a slight diminution of the rate of decline in the birth-rate. Such a view is only an opinion, and so far real knowledge cannot be arrived at until statistical investigation of the family allowance system has reached a much more advanced stage.

BIBLIOGRAPHICAL NOTE

(1) *The Census*

Vauban made an estimate of the number of inhabitants of France as long ago as 1700, and other estimates were made in 1762 and 1764. The first organized census was carried out in 1800, and in the next year, 1801, began the series of censuses, at intervals of five years, which has since been continued, except for the census of 1871, which was postponed for one year, and the census of 1916, which was not held.

When the census forms have been collected, they are first utilized to determine the figures of *population legale* in each commune, i.e. the numbers of persons having their habitual residence in the commune. The forms are then tabulated by the *Statistique Generale de la France*, and the entries analysed by category. The figures of *population presente* are obtained at this stage, i.e. the population actually present in each commune on the day of the census. In 1939 the later calculations had not been completed; only the figures of *population legale* or resident population have been published. These figures have been used in the foregoing account. The completion of the census was not expected until 1940. (See also p. 375.)

The published volume is *Resultats Statistiques du Recensement general de la population en 1936* (Statistique Generale, Paris, 1938).

Summarized statements appear in *Annuaire Statistique, 1938* (Paris, 1939).

(2) *Growth of Population*

The official account of population changes is given in *Statistique du mouvement de la population*, vol. xvi, 1936, Part 1 (Statistique Generale, Paris, 1938). Part 1 deals with marriages, divorces, births and deaths.

Chapter II

PARIS

The Site: The Growth of the City: Inner Paris: Greater Paris: Bibliographical Note

THE SITE

The successive stages in the expansion of Paris from its nucleus on an island in the Seine are closely related to the physical features of its site, and are still clearly embodied in its plan. After receiving the waters of the Maine, the Seine, cutting through a line of low heights, begins the first of its loops towards the north. On the southern bank it receives a small tributary, the Bievre, which after flowing east and north is deflected eastwards again by a low spur, the Mont Ste-Genevieve (Fig. 27). In general the relief on the south bank is broken and of moderate elevation. This broken relief imposed limitations upon the city's early development to the south, but farther to the west near the Champ de Mars a portion of the flood plain allowed expansion. Off the Mont Ste-Genevieve, in the centre of the river, lay a number of small islands, now reduced to two—lie de la Cite and lie St Louis (Plate 10). These islands, and the numerous side branches which originally characterized this stretch of the river, due perhaps to the decrease in the slope of the bed, formed a complicated pattern, but it happened that a line from the southern height across the present lie de la Cite avoided most of the obstacles.

On the north bank, the relief is in contrast to that of the south. A semicircle of heights leaves the river at Charonne on the east, and runs through Menilmontant, Belleville, Montmartre, and Chaillot, returning to the river at Passy. These heights mark the northern slopes of the Quaternary course of the Seine, the loop of which was much more pronounced than that of the present river (Fig. 27). Probably owing to changes in the course of the Marne, which increased the velocity of the Seine, the latter cut off the extremity of this loop to occupy its present course. Thus the area immediately north of the Seine is a segment of a meander plain, originally sloping not to the Seine, which cut a narrow bed through it, but towards the older course. In the early history of the city this was occupied in its western portion by a stream flowing from Menilmontant, and in its eastern end by an area of marshland, Le Marais.

The north bank therefore afforded ample space for expansion, and the growth of Paris in this direction has been closely related to this abandoned river course. At one period, portions of it were incorporated as a moat forming part of the city's fortifications. At times, too, it has proved a source of anxiety to the city engineers, for the Seine in flood has occasionally attempted to reoccupy its former bed. Thus in the floods of 1910 subsoil penetration by this channel flooded large areas round the Gare St Lazare. The original relief, however, has been largely hidden by drainage, by newly-made ground, and by buildings. It is important to note also that the northern ring of heights is not continuous: Montmartre is isolated by gaps to east and west, the former being especially important as it affords an easy line of communication northwards.

The significant features of the site therefore are the approach of the southern hills to the river, the islands in the river bed reducing the difficulty of bridging, the open plain on the north bank, and the breeches in the northern heights. The three main areas—southern heights, islands, and northern plain—have persisted from early days as subdivisions with distinct characteristics associated respectively with Universite, Cite, and Ville.

THE GROWTH OF THE CITY

The Early Medieval City

Before the Roman occupation of Gaul, the Ile de la Cite was the site of a settlement, Lutetia, the centre of a Gaulish tribe, the Parisii. By this time the Seine had been bridged and the island was close to an intersection of routes, a south-to-north land route and an east-to-west river way. Roman observers remarked upon the busy boat traffic on the river. Under Roman administration the principal section of the town was laid out on the southern bank, on the slopes of the Mont Ste-Genevieve. A Roman road from Chartres ran northwards across the lie de la Cite and up through the Montmartre-Belleville gap; on the north bank it was joined by another road descending the valley westwards from Melun, and it was around this junction that commerce was increasingly to centre.

During the first centuries of the Middle Ages however progress was slow. In the disturbed times following the Roman withdrawal and the Frankish advance, when the Roman town on the south bank was destroyed, settlement was chiefly confined to the island with two bridgeheads north and south of the river. Under the Merovingians,

in the fifth and sixth centuries, order was re-established, and with the expanding influence of the Church the elements of civilized life gradually returned. During the reign of Clovis, the basilica of SS. Peter and Paul was built on the southern quarter, and other churches soon followed (St Benoit, St Severin). Settlement on the outskirts was encouraged by ecclesiastical foundations, the abbey of St Germain TAuxerrois on the north bank, and of St Germain des Pres on a former left bank island below the city limits. The surrounding forests were gradually cleared during the ninth century, and with the revival of trade the value of the position of Paris became recognized, by none more clearly than the early rulers of the House of Capet. Indeed, it was their great achievement to establish Paris as the undisputed capital of France. By their efforts the advance of the Norsemen was stayed at the city walls after a siege during which the southern quarter was again destroyed, and their royal duchy, extending north and south of the Seine and conveniently linked by Paris, was welded together to become the foundation of the kingdom of France.*

It was to the centralizing policy of the French monarchy more than to any combination of geographical factors that the city's predominance and extraordinary growth were due. As the seat of the central government, the courts of law, and the great university of the Middle Ages, Paris drew to itself, with increasing attractive power, first the professions and trades necessary to sustain their needs, and later an industrial population to meet the demand for goods as close to the market as possible. Thus the development of Paris has been from an administrative centre to a great commercial market, and finally to an industrial concentration. The development of a planned system of roads, of canals, and of railways merely tightened the hold of Paris on the country.

The effect of this Capetian centralizing policy was soon visible in the development of the city, which during the twelfth century assumed its characteristic tripartite form. The *lie de la Cite* was the centre of royal and ecclesiastical administration. In the middle of the century the building of the new cathedral of Notre Dame was begun, and the church schools formerly grouped around it moved across to the south bank where, around the theological college founded by Robert de Sorbon in 1253, the University and its quarter crystallized. Here gathered, besides masters and scholars, the attendant scribes, followed later by the printers.

On the north bank was the 'Ville,' the predominantly commercial

* For the historical background, see vol. 11, pp. 46 et seq., of this Handbook.

Plate 10. Paris: The He de la Cite

On the island is the Palais de Justice in the foreground, with Notre-Dame Cathedral and the Hotel Dieu near the other end. There is a clear contrast between the congested streets and buildings of the 'Quartier Latin' on the left bank (on right of picture), and the more elegant tree-lined avenues and open spaces of the right bank, where the Hotel de Ville is prominent.

Plate 11. Factories at Billancourt, Paris
The great Renault works extend over a large area and have even spread to the island in the Seine.

quarter; upstream from the bridges, along the creeks and quays, grew the first 'ports' of Paris. The importance of the river traffic, which carried down to the city the wines and timber of the upper Seine basin, is seen from the growing influence of the 'Corporation of water merchants', the head of which became during the thirteenth century the chief civil officer of the municipality. The principal 'port' was on the site now occupied by the Place du Chatelet, near the Hotel-de-Ville, and close to the *croisee de Paris*, the junction of the main routes. Between the water front and the roads were established large markets, an area still partly occupied by the Halles Centrales.

The City Walls

It was around this threefold area that Philip Augustus between 1180 and 1210 built the first city wall (Fig. 27). From the eastern limit of the trading quarter on the north bank it ran in a rough semicircle, the maximum distance from the river being about 800 m., to rest in the west on the recently built fortress of the Louvre. On the south bank it enclosed the Mont Ste-Genevieve, forming the limit of the city in this direction until well into the seventeenth century. The next period of growth was therefore on the north bank, at first eastwards until the marshland along the old course of the river was reached. This marsh was gradually drained and occupied by market gardens to supply the growing city, until it was built over in the eighteenth century. The second important line of fortifications, built by Charles V about 1370, began at the Bastille and incorporated the Louvre on the west. Within the old limits the population had been growing rapidly: on a basis of a census of hearths taken in 1329 it is estimated that the population was then about a quarter of a million, a remarkable figure for the period. The new walls, however, included considerable areas of open land sufficient for some time to absorb growth which at first slackened owing to disturbed political conditions, although by the seventeenth century the city was spreading rapidly beyond the walls, mainly northwards, despite successive royal edicts establishing forbidden zones. These were partly prompted by fears of inability to feed so large a concentration, hence the preservation of the gardens of Le Marais and the attention to the water supply. The city was dependent largely upon water from the Seine, pumped directly from the river at La Samaritaine and the Pont Notre Dame. In the middle of the fourteenth century the population was nearing half a million, a stage in its development which was not materially passed until the industrial era.

The next extension of boundaries had a fiscal rather than a military reason; to facilitate the collection of the *octroi* a wall, the 'Mur des Fermiers-Generaux', was built between 1784 and 1791, with a radius some 1,500 m. larger than that of the preceding wall. This carried the northern limits of the city to the line of the old river course and

Fig. 27. The site and growth of Paris

Based on G. R. Crone, 'The site and growth of Paris', *Geographical Journal*, vol. xcvi, p. 37 (London, 1941). For the work of Philip Augustus, see vol. 11, p. 49 of this Handbook.

the foot of the northern heights. It enclosed the faubourgs which had grown up along the radiating routes and much open land, especially on the south bank. Portions of the old ramparts became the line of the great or inner boulevards.

Throughout the eighteenth century the population did not rise above half a million, but with the progress of the industrial revolution the city again pressed upon its limits. By 1841 the inhabitants

numbered 935,000, and it was then decided for military reasons to fortify a much extended area. The *enceinte* was thrown along the northern heights beyond Belleville and Montmartre and southwards towards Gentilly and Issy. This brought within the limits of Paris a number of considerable towns, for Belleville had at that time a population of 57,000 people, and Montmartre 35,000. With the incorporation in 1861 of the communes thus enclosed, the population of Paris rose to 1,690,000. The wall of the Farmers-General then became the line of the outer boulevards.

Fig. 28. The built-up area in 1839

Based on *Carte des Environs de Paris*, drawn in 1839 at the Depot Generale de la Guerre, under the direction of Lieutenant-General B. Pelet.

Industrial Growth

With industrialization and improved communications, the activities of the population also began to change markedly. Formerly, the occupation of the Parisian workers, apart from the predominating official and commercial classes, had lain mainly in trades requiring traditional skill and taste rather than an abundant supply of raw material. With the building of canals and railways, supplies of materials

for heavier industries, particularly coal and iron, became available and industry was freed from its dependence upon the river front. In the twenties there was an epoch of canal building. The Canal St Denis and the Canal St Martin were followed a few years later by the Canal de l'Ourcq. With the building of the canals the prosperity of Paris became even more closely linked to waterborne traffic, which was handled at various quays and basins along the river and the canal system, while river ports have developed up and down stream from Paris to serve the industrial suburbs, e.g. at Ivry, St Ouen, St Denis, and Gennevilliers.*

Close on the canals followed the railways. On the north bank the gaps east and west of Montmartre served as convenient routes ending at the great termini of the Gares de PEst, du Nord, and St Lazare, placed near the outer boulevards. The area enclosed in 1841 made much land available for building, and around the canal basins and stations gathered warehouses and slaughterhouses, railway goods yards and repair shops, factories and gasworks, with tenements in the neighbouring quarters to house the workers. †

While Paris was thus expanding and its industries growing, wide changes were also being made to the plan of the city. These were initiated by Napoleon III, partly on aesthetic and partly on military grounds, and the work of reconstruction was entrusted to Baron Haussmann between 1854 and 1869. Narrow streets and congested areas gave place to wide boulevards and squares (Place de l'Etoile, Boulevard St Michel); parks and gardens were laid out (Bois de Boulogne); public buildings such as the Opera were erected; and the ring of outer boulevards was built on the line of the wall of the Farmers-General. This work was naturally costly, and Haussmann met with much opposition: it is to his persistence and the emperor's support that modern Paris owes its spaciousness and its vistas.

As a result of its industrial development, the population of Paris grew rapidly after 1861, increasing by 25 % in the next twenty years. From 1881 to 1901 the rate of increase declined to about 20%, and with the beginning of this century the period of rapid expansion was approaching its close. The population reached a maximum in 1921 with a figure of 2,906,000, but this represented an increase in the preceding twenty years of 7 % only. The war of 1914-18 no doubt had

* The waterways serving Paris are more fully dealt with in vol. iv, chapter vi, of this Handbook.

† The railways serving Paris are dealt with more fully in vol. iv, chapter iv, of this Handbook.

some influence on this slowing up of the city's growth, but decline had already set in before 1911. Since 1921, the population has fallen to 2,891,000 in 1931, and to 2,830,000 in 1936, a decline of roughly 2½%. To sum up: the net result of a century of growth, 1839-1939, can be seen by comparing Figs. 28 and 29.

Fig. 29. The built-up area in 1939

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 2 (Paris, 1934), and air photographs.

Water Supply

The growth of the city has been accompanied by improvements in the water supply. Until the nineteenth century, the domestic water of Paris was drawn mainly from wells or from the Seine. The latter was raised by pumps, the first of which, La Samaritaine, was set up at the Pont Neuf in the reign of Henry IV. Later in the seventeenth century other pumps were erected at Notre Dame and at Marly for the supply of Versailles. The public fountains were, however, supplied to some extent with water from other sources, e.g. the Belleville aqueduct, said to date from the fourteenth century, and the Arcueil aqueduct, restored by Marie de Medici. These supplies were

inadequate for the expanding city, and the first step taken to obtain water from a distance was the construction in 1822 of the Canal de l'Ourcq, which for some years served as an aqueduct as well as a navigable canal. About the same time, attempts were made to utilize artesian supplies at Grenelle and elsewhere, but owing to technical difficulties these wells were abandoned. It was not until the Second Empire that the problem was solved by the engineer Belgrand, who laid the foundations of the present system. The earlier superficial supplies, were now used for public and industrial purposes, while domestic water was obtained by tapping adequate and pure supplies at the sources of distant streams; this water was led through aqueducts or underground conduits to reservoirs on the suburban heights. The first to be completed, in 1865, was that from the sources of the Dhuis, a tributary of the Marne, which carries water 114 km. to a reservoir at Menilmontant. Later, water was similarly brought from the Vanne, an affluent of the Yonne, to Montsouris (173 km.), and from the Arvre, a tributary of the Eure, to St Cloud (120 km.). More recently, Supplies for the Montsouris reservoir have been obtained from the Loing and Lunain (73 km.), and the Vanne supplies have been augmented by the Voulzie aqueduct, completed in 1925.

The water from these sources amounts to about 450,000 cu.m. per day, which is still inadequate to meet the demand, especially in summer. Some 300,000 cu.m. have therefore to be pumped from the Seine and Marne, filtered and sterilized at Saint-Maur and Ivry, and either mixed with the other water or retained in separate reservoirs. In addition, very large quantities of river water, distributed through a separate system, are used by public authorities for street cleansing, etc., and by factories, and the maximum amount that can be removed from the rivers is being approached. There have been proposals therefore to seek further supplies from the water-bearing beds in the valley of the Loire, 200 km. south of Paris, which, it has been estimated, could yield 1 million cu.m. a day. It is probable, however, that the cost of the water thus obtained would be greater than that of water from the Seine after it has been filtered and pumped up to the reservoirs. Technical improvements have now made it possible to use artesian water in the outer districts: e.g. the artesian well sunk at Aulnay-sous-Bois in 1933 to a depth of 831 m. yields 5,000 cu.m. a day for the north-western districts.

INNER PARIS

Inner Paris: Population Changes since 1841

The slowing up of the rate of increase and eventual decline in the population of Paris was accompanied by a very rapid growth in the surrounding region, but before dealing with Greater Paris something

Fig. 30

Fig. 31

Fig. 30. The decline of population in the centre of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The decline in the central districts has been most marked in those which lie to the north of the river, particularly in the arrondissement of La Bourse and in the quartier of Les Halles.

Fig. 31. The growth of population in the outer districts of Paris (city), 1896-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 21 (Paris, 1934).

The outer arrondissements of the city have increased considerably in population; more especially those which lie to the south. These areas have a number of light industries, and they also contain the homes of large numbers of the people who work in the heart of the city, many of whom have been displaced from the centre in recent decades. Outstanding among the districts of rapid increase are Clignancourt to the north, Buttes Chaumont and Menilmontant to the east, Vaugirard and Petit Montrouge to the south, and Auteuil and Passy to the south-west.

should be said of the distribution of population within the city limits. The city, that is, the area within the *enceinte* of 1841, plus the narrow military zone around it, the Bois de Boulogne, and the Bois de Vincennes, has an area of approximately 78 sq. km. In comparison with other great cities, this is relatively small, and the average density of population (37,000 per sq. km. in 1931) is consequently high. The administrative County of London, for example, has an area almost four times as great. Towards the end of the century, in 1896, the

corresponding figure was 32,000, so that the increase in density between 1896 and 1931 was 15 %. But this increase was not uniform over the whole city.

Two tendencies have been at work. With the continually increasing scale of operations, the heavier industries which had at first tended to concentrate in the northern quarters of the city began to move outwards into the open country, where ample and cheap sites, well placed for river and rail communications, were available. As a result, the Paris region became one of the most important in France for chemical, textile, and engineering works, and in 1931, 20% of French skilled workers were resident in the departments of Seine and Seine-et-Oise. Another tendency has been the so-called ⁱ 'flight from the centre'. The increasing demand for sites for administrative and commercial offices, banks, large stores, etc. in the centre has led to a rise in land values, and the consequent demolition of old residential property. Moreover, the improved facilities for travel to and from the suburbs have enabled city workers to live at a distance from their work. The insanitary condition of the former densely peopled quarters has also led the municipality to demolish properties and to move the inhabitants to new quarters on the edge of the city. The result of these developments has therefore been to reduce considerably the density of the resident population in the centre of the city, to increase that of the quarters on the periphery, and to bring into existence in the Greater Paris region large industrial and dormitory towns (Figs. 31-33).

Inner Paris: Distribution of Population

Comparing the distributions of 1896 and 1931, it is apparent that Paris can be regarded as composed approximately of three zones with individual characteristics, in which varying tendencies are visible.

The centre of the city, comprising the first seven arrondissements, covers the three historic components of *cite*, *ville*, and *universite*. The most densely populated of these arrondissements is the Temple, with over 50,000 inhabitants per sq. km., followed by L'Hotel de Ville and La Bourse, all on the north bank with 25,000-50,000 per sq. km. These constitute the financial and commercial district, with subsidiary activities such as newspaper production, and have all declined in resident population. This is particularly noticeable in La Bourse, where three of the quarters decreased by more than 35 % between 1896 and 1931. It is significant, as showing the piecemeal nature of this outward movement, that the fourth quarter remains one of the most densely

populated in the city, Bonne-Nouvelle with 101,500 per sq. km., and that the St Gervais quarter of the Hotel de Ville had in 1931 the exceptionally high density of 106,900 per sq. km. The fourth of these arrondissements on the north bank is the Louvre, with a lower density of 10,000-25,000 per sq. km. This includes the central markets (Les Halles), and also an area lying between the Champs-Elysees and L'Opera, which is the centre of 'haute couture', i.e. the production of 'Paris fashions'. The reason for this localization probably lies in the former focusing of court life around the Louvre and the Tuileries. The more popular 'grands magasins' lie between this point and the commercial area. Decline in population has also been very marked here, that of the quarter of the Halles having exceeded 50%. This area is also the home of highly skilled craftsmen, working on a small scale, e.g. costumiers, tailors, gold- and silversmiths, jewellers, and leather workers, who supply the demand for luxury articles.

The portion of the central area south of the river comprises the Pantheon, Luxembourg, and Palais Bourbon. The first two, corresponding to the University and 'quartier latin', had densities of 25,000-50,000 per sq. km.; the third, containing the homes of the aristocratic families of the Faubourg St Germain, of the diplomats in the shadow of the Quai d'Orsay, and of retired officials, is less heavily populated (10,000-25,000 per sq. km.).

The second zone, on the north bank, includes the arrondissements of L'Opera, L'Enclos-St Laurent, and Popincourt. This is the area of the Gares St Lazare, du Nord, and de l'Est, of the Canal St Martin, and consequently of commercial and manufacturing activity. Thus L'Opera and Popincourt were two of the three arrondissements which still retained in 1931 densities greater than 50,000 per sq. km. The quartier Rochechouart of L'Opera had the high density of 90,300 per sq. km., and was the sole area in this zone which increased during this period. The decline elsewhere was largely due to the spread of business houses and luxury shops in this direction from the centre: as a result, one district adjacent to La Bourse, the 'quartier de la Chaussee d'Antin', had decreased by more than 50%. The decline was less marked in Popincourt, which is largely a district of workers' tenements, with a large foreign element.

The third zone is that of the outer ring of arrondissements, mainly industrial and working-class areas, e.g. Batignolles, Montmartre, Chaumont, and Vaugirard, with a density in general between 25,000 and 50,000 per sq. km. This ring is broken at one point in the south-west by wealthier residential districts on the heights of Passy. Save

in a few minor districts, the population of this zone increased markedly since 1896. High increases of over 150% occurred in the manufacturing area of Vaugirard, and in Passy; several other quartiers increased by 65-120%. Though not the scene of heavy industries

Fig. 32. The density of population in the department of the Seine, 1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 20 (Paris, 1934).

In the city itself the greatest densities are found to the north of the Seine. In the remainder of the department the principal area of high density lies to the north-west on both sides of the Seine—at Neuilly, Clichy, Puteaux, Courbevoie and Colombes. This distribution largely reflects the distribution of industry in Greater Paris. B, Bois de Boulogne; V, Bois de Vincennes.

similar to those of Greater Paris, these exterior arrondissements have a variety of industries, such as the furniture factories of the Faubourg St Antoine (Batignolles), the boot factories of Belleville, and the light metal works of Charonne, apart from those more directly associated with the railways. These areas are also the homes of those displaced from the centre who work daily in the city and the west.

GREATER PARIS

Growth of Population

The boundaries which should be assigned to Greater Paris are not easy to determine precisely. During discussions in 1932 on future

Fig. 33. The growth of population in outer Paris, i.e. the department of the Seine outside the city limits, 1876-1931

Based on A. Demangeon, *Paris; la ville et sa banlieue*, p. 22 (Paris, 1934).

While the increase has been fairly general, it has been most marked to the north and north-east, and in some areas to the south. It will be noted that these areas lie mostly away from the city limits, for by 1876 the communes immediately adjoining Paris had already begun to experience a growth of population spreading outward from the city. These more remote communes, such as Gennevilliers and Colombes to the north-west, La Corneuve, Le Bourget, Drancy, Aubervilliers, Pantin, Bobigny and Villemomble to the north-east, and Gentilly, Villejuif and Sceaux to the south, had very small populations in 1876, and with the spread of industry in recent decades their growth has appeared all the more striking.

growth it was declared to consist of the department of the Seine, those communes of Seine-et-Oise and Seine-et-Marne within a radius of 35 km. of Paris, and a large proportion of L'Oise, forming an area

of approximately 5,000 sq. km. with a population of 6,300,000. This deliberately included areas not then dominated by Paris: but whatever the exact boundaries, there is no doubt that the whole of the department of the Seine falls within Greater Paris, and recent censuses show how rapid has been the growth of its population. In 1881 the department, excluding Paris, had 530,000 inhabitants: this figure, by 1901, had nearly doubled (956,000), and trebled by 1921 (1,506,000); by 1936 it was 2,133,000, comparable with that of the city itself, with an average density of approximately 5,300 per sq. km. (Figs. 32, 33).

Development in these outer regions has spread along the lines of communications, absorbing long-established towns, and generally repeating the characteristics of the city's quarters thus extended—industrial areas on the lower, more accessible land, and residential suburbs on the higher. Four industrial areas are conspicuous: * (1) the north and north-eastern, comprising St Denis, St Ouen, Aubervilliers, and Pantin; (2) the west and north-western, spread along the winding valley of the lower Seine (Fig. 34); (3) the south-eastern, in the upper Seine valley as far as Choisy and extending west to the valley of the Bievre; and (4) the south and south-western, adjoining the city limits in the Gentilly, Vanves, and Arcueil areas, and extending westwards to Issy-les-Moulineaux.

North and North-eastern Industrial Suburbs. The first of these is of considerable importance. The basis of its development has been the St Denis canal, which, via the Canal de l'Ourcq, brings Pantin on the east within the area. The important industries of St Denis produce locomotives and wagons, engineering and electrical equipment, acids, fertilizers, soaps, etc., and along the Seine ships and barges are built. St Ouen to the south has a number of very diversified industries, generally of a lighter character—copper and aluminium

* For details of industry, see pp. 177-9.

Fig. 34. The industries of Greater Paris, 1939

Based on (1) *Carte Industrielle de la Region Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The line of the 1841-5 fortifications is represented by the circular line of railway, except to the east where it is marked by a belt devoid of factories. Thus to the north, north-west and south-west most of the factories lie outside the city limits, while to the east and south they lie more within them. It is clear that the location of the larger factories is much more closely related to the river and to the railways than to the canals. The Port de Gennevilliers is a barge port of recent construction, in which the two existing docks will be followed by others, the whole system being designed to serve the growing industries of Colombes, Gennevilliers and Argenteuil.

goods, tinned foods, furniture and pianos, gloves from skins. The industries of Aubervilliers, La Courneuve, and Pantin are predominantly chemical, ranging from oil refining to perfumes and toilet articles, while the by-products of the Villette slaughterhouses are used for the manufacture of tallow, margarine and leather. In these districts the available labour has attracted many minor factories,

These include mechanical and constructional engineering and a variety of metal manufactures. The majority of these factories lie to the east and south.

producing, for example, glass and pottery at St Denis, and sewing cotton and tobacco at Pantin. These five communes form a block of over 240,000 inhabitants, which increased between 1921 and 1936 by approximately 15%, despite a marked decline in the depression following 1931. This manufacturing area is spreading north-eastwards towards the rail and air centre of Le Bourget, competing for the available land with the builders of housing estates, who have been particularly active around Drancy (Figs. 28, 35).

West and North-western Industrial Suburbs. The second great industrial group is in the west and north-west, established along the valley of the Seine. Immediately west of Paris is the centre of the French motor and aircraft industries, with the Citroen works at Grenelle and the Renault at Boulogne-Billancourt (Plate II). Here

Fig. 36. The electrical, automobile and aircraft industries of Greater Paris, 1939 Based on (1) *Carte Industrielle de la Région Parisienne*, 1/20,000, 4 sheets (Paris, 1933); (2) *Carte Industrielle de la Grande Banlieue*, 1/320,000 (Paris, 1927); and (3) official sources.

The concentration of these industries to the north-west and south-west is clear. Figs. 35 and 36 are complementary, and show between them all the metal-using industries. Fig. 35 shows mainly old-established industries; Fig. 36 shows newer industries.

expansion has been rapid, the population of the latter commune having increased from 68,000 in 1921 to 97,000 in 1936. Farther downstream, on both sides of the valley, extends a string of industrial concentrations combining the engineering and manufacturing activities of their neighbours to the north and south: Suresnes, Puteaux (armaments), Courbevoie, Levallois-Perret (motors and aircraft), Clichy (gas works and oil refineries along the river), and Asnteres (chemicals

and foodstuffs). The population of this zone exceeds 380,000, having increased by approximately 20 % between 1921 and 1936. Expansion has progressed in the loop of the Seine towards Argenteuil, notably around Gennevilliers, where there is a large electric power station fed by water- and rail-borne coal. Interlaced with these and standing on the higher ground are residential suburbs, e.g. Neuilly, Nanterre and Colombes (Fig. 36).

South-eastern Industrial Suburbs. The industrial areas are repeated on a somewhat smaller scale in the south-east along the Seine valley through Ivry and Vitry, where there are large power stations and gasworks. Vitry, however, still continues to grow flowers for the city markets, whilst Choisy manufactures linoleum, paper and china. Here live a population of some 120,000.

South and South-western Industrial Suburbs. Another industrial belt extends to the west, skirting the city limits as far as the Seine; its features are the tanneries and laundries in the valley of the Bievre around Gentilly which perpetuate the early use made of its waters, and Issy-les-Moulineaux, with its power stations, munition and cement works, breweries, and tobacco factories. This sector has a population of over 200,000. From its western end a series of small towns continue southwards over the broken plateau, and house thousands who work daily in Paris; these towns, interspersed with market gardens, carry the boundaries of Greater Paris beyond Sceaux. The recent electrification of the railway line serving this area may be expected to stimulate the further development of dormitory estates.*

Eastern Residential Suburbs. In this circuit of Paris one sector has so far been omitted, the eastern, which has become the predominantly residential area of the outskirts, beyond the factories along the eastern border of the city. Extending over the gentle and formerly wooded hills north of the Marne as far as the boundary of the department are numerous residential towns such as Vincennes, Montreuil, and Fontenay-sous-Bois, with islands of orchards, vegetable and flower gardens, scarcely touched by industrial development. Nearly a quarter of a million people have their homes in this sector of Greater Paris. Similar expansion has taken place along the valley of the Marne, the tide of building progressing from one loop of the river to the next as far as Nogent. The peninsula between the Seine and the Marne is occupied by the working-class suburb around Alfortville comprising some 75,000 inhabitants. In the first great loop of the Marne is the garden city of St Maur (57,000); in the next Champigny (27,500),

* See vol. iv, chapter iv, of this Handbook.

and again in the next Nogent and Le Perreux (together 45,000), developments all consequent on the breaking up of large estates towards the end of the last century. Market gardening is still carried on to some extent, but except around Alfortville and Maisons-Alfort there has so far been little industrial development.

Regional Planning

This development of the Paris region has been haphazard and unco-ordinated. Factories and housing estates are intermingled: the new quarters of the expanding towns are often unprovided with adequate roads, drainage, or water supply: valuable agricultural land has been built over: and natural amenities have been destroyed. This has resulted from the lack of a central authority, the constituent communes being largely independent and without the means to develop in an orderly way. In 1932 a law prescribing a 'projet d'aménagement' for the whole region was promulgated. A general directing plan was drawn up and presented in 1934, with which the local schemes were to conform. It covered the lay-out of the main roads, open spaces, the use of the land and the regulation of buildings, public services, and the protection of sites. The scheme for communications provided for five radial motor roads in conjunction with an outer ring at a distance of some 20 km. from the centre.* For several reasons, among which the conflict of local interests is not the least important, progress with the scheme has been slow.

Attempts have also been made from time to time to check the continued concentration of industries, particularly aircraft works, in the Paris region, as this was considered to be strategically dangerous. In 1931 a fund was instituted to assist the removal, if required by the Air Ministry, of aircraft factories to a particular zone, and the scope of this measure was afterwards enlarged. Three years later the Departments of National Defence ruled that works thereafter established in the region should in general be excluded from their supply lists, and in 1938 official approval was required for the siting of new munition factories. It does not appear that this movement had made any considerable progress before the outbreak of war, one obstacle being the disinclination of the workers to migrate with the factories.

BIBLIOGRAPHICAL NOTE

AGRICULTURE

Introduction: Wheat: Other Cereals: Root Crops: Minor Crops: Wine and other Beverages: Market Gardening: Livestock: Working Population: Land Tenure: Legislation: Forests: The Vichy Regime: Bibliographical Note

INTRODUCTION

France is a country highly favoured by nature from the point of view of agricultural production. Of its working population, 35% are engaged in agriculture, and the urban areas are to a great extent fed by home-grown food. A map showing density of population exhibits a remarkable continuity in distribution; only in the highest parts of the Alps and the Cevennes and on the sandy forested stretches of the Landes are there any considerable empty areas. Cultivation penetrates far into the highlands of the Alps, the Vosges and the Jura, following the terraces of the river valleys; it covers the lower platforms of the Central Massif; it renders return, however meagre, even to the dense population of the poor acid soils of Armor in Brittany. If pastoral pursuits and forestry are included, there is hardly a corner of the country left unproductive.

Climate, soil and relief have greatly contributed to this high degree of land utilization, and to these factors must be added the late development of French industry. Both climatic and soil conditions present considerable variety. Exposure to Atlantic winds precludes the harsh winter conditions of more northerly and more continental areas, so that the sheltered bays of the Breton coasts are able to grow early vegetables for export. The extension southwards to Mediterranean shores and the protection afforded by the Cevennes and the Alps against northerly winds give to France a share in Mediterranean products, and have made possible the large-scale cultivation of *pruneurs*; yet, except in the Rhone delta and the eastern-facing valleys of the Pyrenees, the summer drought is not sufficiently prolonged to make cultivation entirely dependent upon irrigation. In the east of the country there is an approximation to continental conditions of agriculture, with the cultivation of maize, hops and tobacco in the lowlands. Finally, the ample development of mountain and plateau in the south and south-east with Atlantic-facing slopes is the basis for pastoral and forest industries.
